STATE AND LOCAL BOARD OF HEALTH[1]

BY JOHN AVERY, M D,

OF GREENVILLE, MICHIGAN

The State is charged with no higher duty than that of protecting the health and lives of its citizens. Its wealth is not so much in its soil, its timber, and its minerals, as in the ability of its citizens to develop these sources of wealth.

The theory of our form of government, and in fact of every form of enlightened government, is that each citizen is required to yield up a portion of his personal rights, that the general good of all may be conserved. In return for this surrender of individual liberty, the State undertakes to make him secure in his person, and in the undisturbed possession of his property. This security of person and property implies the right to labor in his own chosen calling, undisturbed and unhindered by another, so long as his calling is legal, and does not trespass upon the rights of any other citizen. It secures to him and to his family the fruits of that labor, and protects him and them in their enjoyment. And it gives him that sense of security which can only arise from a belief that his neighbors will respect his rights as he respects theirs, or that the State will interfere to restrain and to protect. The poor man's health is his capital, and the wages of each day's labor is the interest that capital pays to its owner. It is as much the duty of the State to protect that capital, and make the owner secure in its possession and enjoyment, principal and interest, as it is to protect a railroad corporation in its franchises, or a lottery company in its schemes.

And so the laws of all just government hold a man responsible for an injury done another, that disables him from labor, to the extent of the injury done, through carelessness, negligence or malice. Ignorance of the law may sometimes mitigate an offence against personal rights, but it can never justify it. A man must exercise the same care to protect another from injury or loss, as a prudent man would take to protect himself under like circumstances. In most if not all the States, these general principles have been embodied into the statute laws, and constitute the guarantee of the commonwealth to the citizen, that it will protect his life, his family, his property and his personal rights. And so we have laws to secure the safety of persons, while traveling on railroads, steamboats and other public conveyances, to give them reasonable protection while stopping at hotels, while attending theatres, concerts, and other places of public gatherings, to protect the employés of large manufacturing establishments, and the occupants of tenement houses, and to prevent the unnecessary spread of diseases which endanger the health and lives of the citizens of the State.

The latter are known as the public health laws of the State, and under them, the man who either intentionally or carelessly, exposes his neighbor or his family, to disease which interrupts his business or employment, and subjects him to pecuniary loss, is equally a violator of the law, or should be made such, as he who inflicts loss from exposure to fire, from accident while travelling on railroads, or attending any place of public resort, or at work in any mill or factory, or while residing in any tenement house.

In Michigan, and many other States, to give effect to these laws, to see that they are properly enforced and observed, the State has created a State Board of Health, and a local board of health in each municipality in the State. The duties of the State Board, under the law, are supervisory and advisory. "They have the general supervision of the interests of the health and life of the citizens of the State." They are commanded to "study the vital statistics of the State, and to endeavor to make intelligent and profitable use of the collected records of deaths and sickness among the people, to make sanitary investigations and inquiries respecting the causes of diseases, and especially of epidemics, the causes of mortality, and the effects of localities, employments, ingesta, habits and circumstances on the health of the people. They shall, when required, or when they deem it best, advise officers of the government, or other State Boards, in regard to the location, drainage, water supply, disposal of excreta, heating and ventilation of any public institution or building."

They are required to communicate with other State Boards of Health, and with local boards of health within the State, and to prepare blank forms of returns, and such instructions as may be necessary, and forward them to the clerks of local boards of health throughout the State. They shall collect information concerning vital statistics, knowledge respecting diseases, and all useful information on the subject of hygiene, and through an annual report, or otherwise as the Board may direct, shall disseminate such information among the people.

---

[1] Read in the Section of State Medicine at the Thirty Sixth Annual Meeting of the American Medical Association.

And the law further provides that the members of the Board shall receive no compensation for their services, except traveling and other necessary expenses while employed on the business of the Board. This is undoubtedly a wise provision, and I would most earnestly recommend its adoption in every State where the physicians are all rich, and the people all poor. The State furnishes office room for the use of the Board, and authorizes the employment of a sufficient number of clerks to do the large amount of work which comes into the office of the Secretary, and makes a reasonable appropriation of money each year to defray all necessary expenses of the Board. During the twelve years since the organization of the Board, they have prepared, printed and circulated among local boards of health, health officers and the people over 500,000 copies of monographs on different subjects relating to public health. They have collected records of sickness and deaths in different parts of the State, and given the results back to the people of the State. They have inquired into the causes of local epidemics and warned and advised communities. They have investigated special causes of sickness, such as poisonous cheese, diseased meats, poisonous wall paper, adulterated foods of various kinds and impure water. They have visited various places in the State where nuisances have been reported to them by aggrieved citizens, and advised as to the remedy in such cases.

They have visited, at the request of the State Board of Correction and Charities, poor-houses and jails in different counties in the State, called attention to their defects and suggested how they could be improved. They have visited the prisons and other State institutions, at the request of their officers and boards of control, to advise how their condition could be bettered. And their advice has uniformly been kindly and courteously received, and often acted upon to the improvement of such institutions. They have examined plans of public buildings about to be erected, and suggested alterations in methods of heating, ventilation, lighting, drainage, plumbing and safety in case of fire. And these suggestions have generally been thankfully accepted and acted upon by architects and builders. The result of these examinations of the plans of public buildings is, that not only the State has buildings better adapted to the purposes for which they are designed, but more attention is being paid to these details in building public halls, school houses, churches and private residences. And thus the comfort, safety, and health of the people of the State is being better secured.

In addition to these prescribed duties of the Board, they have endeavored to awaken a more general interest among the people in sanitary matters, by inaugurating and conducting a series of Sanitary Conventions in the principal cities and villages of the State. These conventions are held under the direction of the State Board, aided by a committee of the citizens in the locality where they are held. Persons interested in sanitary work in each place, and throughout the State, are invited to prepare and read papers upon, and participate in the discussion of such subjects as the particular locality is most interested in. Local papers advertise these conventions, and publish the programmes, in this way the people become interested, and the attendance is generally good. The papers read at these conventions, and a synopsis of the discussions elicited, are printed in pamphlet form and distributed gratuitously among the people. Local health officers in the vicinity quite generally attend these conventions, and take home with them an increased interest in their work. In this way the people are gradually being educated, health officers instructed, and local boards of health are each year becoming more and more efficient.

The State Board of Health is in direct and frequent communication with every city, village and township in the State, through their local boards of health and health officers. They act as a sort of central signal station to which signals of alarm and distress are sent from all parts of the State, and from which warning is sent to the endangered and advice and aid to the afflicted.[1]

The local boards of health are charged with the duty of administering and enforcing the laws relating to the public health. That they have been stimulated and stirred into activity, through the efforts of the State Board, is not to be questioned. And the benefits secured to the people of the State in this direction are perhaps greater and can be more readily appreciated, than in any other. Before the organization of the State Board these local boards, existed scarcely more than in name. They rarely if ever met as a board, made no reports, and in fact, many township and village officers, never knew, that by virtue of the offices they held, they were members of a board of health. Now all this is changed, and we have in place of these inanimate bodies, live, active and working boards of health in most of our cities, villages and townships.

They are required by law "to make annual reports to the State Board," and most of them through the local health physician, report weekly. They are required by law, "to appoint and to constantly have a health officer, who should be a well educated physician, and who shall act as the sanitary advisor, and executive officer of the Board." And in townships where it is not practicable to secure the services of a well-educated and suitable physician, the board may appoint the supervisor or some other person as such health officer. And they shall regulate and audit all fees and charges of persons employed by them in the execution of the health laws, and of their own regulations. And within thirty days after each annual meeting, the Board of Health shall meet for the transaction of business, and shall appoint or reappoint a health officer, and report his name to the State Board, together with his address and a statement whether he is a physician or not. Special meetings are held upon the call of the President or any two members of the Board. They shall make special reports to the State Board whenever required to do so. They shall give public notice of all regulations made by them, and such notice shall be deemed legal notice to all persons. And the health officer, shall, on the receipt of information of a case of small-pox, diphtheria, scarlet fever or other communicable disease dangerous to public health, keep the President of his own board and Secretary of the State Board of Health, constantly informed in respect to such outbreak of disease, and of all the facts, so far as they shall come to his knowledge, respecting sources of danger from any such diseased person or infected article being brought into or taken out of his township, village or city. The local board shall make such regulations respecting nuisances, sources of filth, and causes of sickness within their respective municipalities as they shall judge necessary for the public health and safety. Whenever they shall think it necessary they may enter any building or vessel in their jurisdiction, for the purpose of examining into and destroying, removing or preventing any nuisance, source of filth or cause of sickness. They may make such rules and regulations in relation to the care and cleansing of privies and water-closets, as they may deem desirable for the preservation of the health of the inhabitants—or they may declare any such privy or water closet a nuisance, and order its abatement.

---

[1] A recent law, requiring the study of physiology and hygiene with especial reference to the effect of alcoholic stimulants upon the human system in all our common schools provides that all text books upon these subjects shall be submitted for approval to the joint action of the State Board of Health and the State Board of Education. In pursuance of this provision a large number of text books have been examined and some approved and some not approved.

When they shall judge it necessary, they shall assign certain places for the exercise of any trade or employment offensive to the inhabitants or dangerous to the public health, and forbid the exercise thereof in places not so assigned. Whenever a health officer shall receive reliable notice, or shall otherwise have good reason to believe, that there is within his township a case of small-pox, diphtheria, scarlet fever or other communicable disease dangerous to the public health, it shall be his duty to immediately investigate the subject, and to order the prompt and thorough isolation of those sick or infected with such disease, so long as there is danger of communicating it to other persons, and to see that no person suffers for the want of nurses or other necessaries because of isolation for the public good, to give public notice by placard, and to promptly notify teachers or superintendents of schools concerning families in which are contagious diseases, to supervise funerals of persons dead from any communicable disease, to disinfect clothing, rooms and premises, and all articles likely to be infected, before allowing their use by persons other than those in isolation. And this well-educated physician, health officer and sanitary adviser, shall receive for his services a sum of not less than two dollars *per diem*. This is another wise provision, particularly commended to the attention of other States. In justice to Michigan, however, I will state that this does not prevent local authorities from fixing the salary of the health officer at a larger sum.

Local boards of health, shall provide hospitals, or some suitable place for the reception and treatment of persons sick with infectious disease, dangerous to public health, and remove persons so infected when public safety demands, or they may consider the house in which the person is taken sick a hospital, as the condition of the patient and the public safety may seem to demand.

By this summary, it will be seen, that the law confers upon local boards of health ample authority, to make and enforce any regulations necessary to protect the citizens of their respective municipalities, against the spread of any communicable disease dangerous in its character, to limit it to the first cases infected, and in the end, to stamp it out. It provides penalties for the violation of any of their regulations or ordinances, and also for the non-performance of duties. These local boards, then are the administrators of all our public health laws, and to their intelligence, zeal and activity in enforcing these laws must the people of Michigan look for security against the spread in their midst of all infectious diseases, and avoidable sources of disease, which endanger their health and lives, and entail suffering and pecuniary loss upon every community they smite.

Nor does the law relieve from responsibility the citizens of the State in regard to the means by which disease is communicated. It requires every householder, hotel keeper, keeper of a boarding-house, and tenants who shall have knowledge of the presence of any communicable disease, in his family, hotel, boarding-house, or on his premises, to give prompt notice of the fact, to the health officer, president or clerk of the board of health of his township, and if he shall neglect or refuse to immediately give such notice, he shall forfeit for each offence, a sum not exceeding one hundred dollars. And it is the duty of the supervisors and presidents of local boards to see that this provision of the law is complied with.

Thus the law in Michigan is very specific in defining the duties of both the State and local Boards of Health. It confers upon the State Board no executive authority, but makes it simply an educative and advisory Board in all matters relating to the public health, and leaves the enforcement of all our public health laws in the hands of the local boards of health. This has proved very satisfactory in that State, and is perhaps, under our form of government, the wisest and safest distribution of authority that can be made—leaving as it does, the enforcement of the public health laws, where it does the enforcement of all other laws for the protection of individuals and communities, in the hands of the local authorities. The State Board represents a larger constituency, and its advice is received and acted upon more readily, than that of any of the local boards. As the whole is greater than any of its parts, so are the utterances of the State Board, representing as they do the whole State, more authoritative than those of any local board. These local boards report to it, and it is the medium through which these reports are summarized and the information afforded by them given to the people.

In each State there are particular diseases and sources of danger, which threaten the public health. In the Southern States, yellow fever, in our sea-board cities and States, Asiatic cholera. In the Eastern and older States, typhoid, and typhus fevers, while in the Northern and Western States, scarlet fever and diphtheria are the particular scourges which afflict the people and demand the untiring vigilance of both State and local boards of health These, unlike most other contagious diseases, delight to strike down the young of our land, and on that account, seem the most unnatural of all the fatal dangers that threaten us In Michigan, the State Board has made an unrelenting warfare upon them, and the people are beginning to demand of the local authorities, the same protection against their spread as they do in an outbreak of small pox They know that small-pox is contagious, and they keep away from it, and insist that the infected shall be kept away from them Through the efforts and educational influence of the State Board, they are beginning to realize that scarlet fever and diphtheria are equally contagious, and much more dangerous to life, and they demand the same protection from them that they do from small-pox

Three years ago, small-pox broke out in a lumber camp, but a few miles from where I reside Nineteen persons had it, and one died At the same time, and in an immediate neighborhood, scarlet fever made its appearance, with a total of twelve cases, and five deaths The people of the country, for miles around, were excited and alarmed about the small-pox, but paid little or no attention to the scarlet fever But a few weeks since, in the same neighborhood, diphtheria was introduced into a family of eight children, and while six of the children died, the disease was not allowed to spread beyond that family Its presence was immediately reported to the local health officer and to the State Board of Health The house was placarded, and quarantined, and every precaution taken to keep the disease within its original limits, and while mourning continues in that household, the community is saved from the further spread of that most fearful scourge

Perhaps this incident in this particular community fairly represents the change in public sentiment throughout the State, in regard to the contagiousness of diphtheria and scarlet fever, and the means necessary to prevent their spread This change is due to the better information of the people in regard to this class of diseases, and this information has been furnished the people through the agency and efforts of the State Board of Health But the people are forgetful and neglectful, and need to be constantly reminded of the sources of danger which threaten their health and lives "Line upon line and precept upon precept," is as necessary to promote public sanitation as it is to promote public and private morals

Constant advice and warning are needed, and in no way can these be furnished the people so generally, so authoritatively, and effectively as through the medium of a well organized and well conducted State Board of Health The obligation of the State to protect the health and lives of its citizens is plain And in no way can it so well perform this duty, as by incurring the small outlay of money necessary for the maintenance and effective working of a State Board of Health

ON THE RELATIONS BETWEEN CELLS AND MICRO-ORGANISMS[1]

BY AUGUSTUS C BERNAYS,

A M M D HEIDELBERG M R C S ENGLAND F R M S, LONDON

Member German Society Surgeons of Berlin Professor of Anatomy St Louis College Physicians and Surgeons

The circular of our Secretary requesting contributions from the members, brought this body of workers into my consciousness, and mindful of the liberality of its constitution and of the earnestness of its purposes I decided to offer the following study at this meeting My subject is not in direct connection with sanitary science, but inasmuch as it treats of vital questions which underlie our progress in medical science of the present times, I trust it will claim your attention

The greatest step forward that was ever taken at one time in medical science was by Rudolph Virchow in the years 1855–1858, when he finished his classical work on "Cellular Pathology" It is not saying too much to claim that on the recognition of the cell theory and its application to pathology is built the entire structure of modern medicine, surgery and hygiene Recognizing the immense benefit which has accrued to mankind from this doctrine, I propose now to inquire into the facts upon which it is based and to ask in which way further progress may be expected

1 "*A cell is a living body consisting of two bladders, the one within the other of different chemical constitution*" Virchow

2 "*Omnis cellula e cellula*" Virchow

3 "*All living things correspond in the one point, that they originate from a cell*" Virchow

4 "*The cell is the simplest form of life manifestation*" Virchow

5 "*Life is confined to a definite form, the cell*" Virchow

6 "*Without a cell there is no life*" Virchow

The above six sentences are quoted from Virchow's "Gesammelte Abhandlungen zur Wissenschaftlichen Medicin," pag 22, Frankfurt-on-Main, 1856

The commanding influence of Virchow on modern pathological and biological research has so far controlled the opinions and thoughts of European scientists, of whom at least four-fifths are his own disciples, that the above theses have entirely entered into the bone and sinew of the students of natural sciences Until very recently they have gone unchallenged, except by a very few, and the objections have as yet made little or no impression, as can be seen by a glance at the first pages of any text book of pathological anatomy or biology published during the past ten years

In a paper purporting to treat of cells, it is proper that we should define this term If we cannot define the term, it loses its usefulness The definitions given by Virchow above are insufficient, since we know innumerable instances of living solitary organisms that do not fulfil the postulates For instance, a micrococcus is certainly a living being, but it is no bladder, nor has anybody ever seen a bladder shaped substance within it I chose this instance at this place, because *I expect to prove that the group of micro organisms, which we call schizomycetes, cannot be classed under the head of what any author up to this day has ever defined to be a cell* When Virchow says that "Without a cell there is no life" he *defines* nothing, the statement is of about as much value as if he had said, *Without protoplasm there is no life, or without albumen there is no life* Such statements are purely hypothetical, they are illogical, because they involve unknown quantities *i e* cell, protoplasm, albumen, and finally they are not postulated by any thing I have just shown that Virchow's definition of a cell would exclude the micro organisms, but no one will doubt that they are living bodies

---

[1] Prepared for the American Public Health Association Dec 1885

C Gegenbaur, one of the most acute and logical thinkers among morphologists defines cells as follows "Cells consist of a small lump of soft living substance, which encloses a more compact body, the nucleus" This definition would also exclude the micro organisms of the group of the schizomycetes The text books of Frey, Orth, Toldt, W Krause and others have accepted the definition of Max Schultze, who defines the cell-substance or protoplasm as a homogeneous, glassy transparent ground-substance, of a semi fluid (soft-waxy) consistency, held together by virtue of this property, with a nucleus, a nearly homogeneous, globular, almost solid body, containing a shiny nucleolus This definition fits the schizomycetes just as little as did the two former We must therefore conclude that these organisms are not cells at all But they are living beings Therefore life is not confined to the definite form called a cell, neither is the cell the simplest form of life-manifestation, and there certainly is life independent of cells

Before entering more deeply into the question regarding the proper definition of the notion cell we must examine what the term protoplasm means This question is not easily answered, since the word is used promiscuously by different authors to mean very different things Confusion reigns in regard to the meaning and use of this word to such a degree that a definition is impossible Some use the word to designate all living and acting substance, the whole substance of the cell including the nucleus, but excluding the cell-membrane, if one be present Others mean by protoplasm only the substance of the cell minus nucleus and membrane Others again use the term only in regard to indifferent or young cells, and do not apply it to the substance of cells which have become specifically differentiated It appears very difficult where to draw the line in these cases between protoplasm and differentiated or higher cell substances But few call the cell substance of muscle cells, or of red blood corpuscles *protoplasm*, whereas most histologists speak of the protoplasm of ganglion or cartilage or connective tissue-cells Should any one attempt to answer the problem, whether any given cell substance is protoplasm or when it is no longer protoplasm, he will find himself unable to respond, simply because no one knows exactly what protoplasm is The recent researches on protoplasm or cell substance by Fromman, Arnold, and especially by Walter Fleming, on whose works I have largely drawn for the present essay, have shown that there is a definite structure in protoplasm morphologically speaking This question, as to the nature of protoplasm has also been studied by Heitzman, and he has arrived at the remarkable conclusion, that the entire body of all animals is one connected mass of protoplasm Stricker has even denied that cells have definite boundaries These last two hypotheses or discoveries, as they are claimed to be, by their authors, directly contradict the experiences of 99-100ths of all observers, and I have seen nothing which would lend even the slightest countenance to such statements Protoplasm has been analyzed chemically and has been found to consist of albuminoid substances, it is said to be contractile, but that is not proven of everything which is called protoplasm The protoplasm theory says "Protoplasm is living material, all life and all organic forms are limited to it and are its products" Does this proposition deserve the name of a theory? Considering that we cannot define the word protoplasm better than the above sentences have shown, is not this theory virtually a *petitio principii*, as much, and even more so, than we were able to show the cell theory of Virchow to be

Our conclusions thus far might be called iconoclastic, although strictly logical and scientific They deserve this appellation unless we can show how the errors just found, may be avoided by future investigators, or if we can advance a better hypothesis in the place of the old ones

It cannot be my object now to enter upon a description of all the methods employed by me to establish the following facts, upon which I will base the conclusions of this essay I reserve these details for an extensive paper, which I shall publish at another time I can merely give some of the facts and results arrived at

During the past five years two particular subjects in microscopical science have chiefly engrossed the thoughts of all progressive workers in this branch The first one was the morphology and physiology of micro organisms, which term I use to include schizomycetes and micrococci only The second was the morphology and physiology of cell protoplasm and cell nucleus, especially the phenomena of karyokinesis, or the division of the nucleus and the structure of cell-substance During my studies on the subjects, I was first of all impressed by the observation that the so called bacteria or micro organisms can in no way be compared to what in histology of the higher animals are called cells Following up this impression by micro chemical experiments, I soon became convinced that the reactions of the cell-substance or protoplasm in no way corresponded to the reactions of bacteria or schizomycetes under the same treatment This fact, however, is well established by many investigators I found, also, that the chemical reaction of the micro organisms closely corresponds to the reaction of the nuclei contained in the cell substance, in fact, that it must be very similar to the substance we call nuclein During the summer of

1884 I spent many days and nights examining and cultivating micro organisms of different kinds In many of my open air cultivations with hay infusions I made the discovery, that there are organisms which can only be called free living nuclei This observation has been made by a few investigators before me, but has always been denied or disputed by others I am ready, however, during any summer, to demonstrate and cultivate these organisms to the absolute satisfaction and conviction of even the most skeptical person In these infusions I not only found free living nuclei, but I saw organisms in almost all stages between a free living naked nucleus to nuclei which were surrounded by a complete shell of protoplasm or cell-substance I also saw nuclei which had a single protoplasmatic cilium, which they used as an organ of locomotion Others of these nuclei had three, still others had as many as fifty cilia arranged around their circumference I could plainly see how a small speck of protoplasm attached to one side of these free nuclei would develop into a hair or cilium, during a few hours that were occupied in the observation of a single organism I could also plainly discern that within the free living nuclei there were smaller dark bodies, some of spherical, others of bacillar shape, which were in constant lively motion I am sure also that I often saw them arrange themselves into rather regular figures previous to division I never succeeded in observing an entire process of division either in a free living nucleus or in an isolated living cell The cause of this was that I could not keep the organisms alive long enough by any means at my disposal I can, however, corroborate the observations of Walter Fleming regarding the process of nuclear division on hardened specimens to the very utmost detail Another observation that I can state with certainty is that the movable bodies contained within the nucleus sometimes leave the body of the nucleus and swim away from it under the cover glass in the water or solution of nutritive salts I also saw bodies which evidently were micro organisms, either bacteria or micrococci, enter into these free nuclei, probably through the same pores or holes in the nuclear membrane through which the others had just left the nucleus

During the summer of 1885 I spent many hours in experiments, conducted with a view to solve the problem as to what would become of a living cell if left to die in a sterilized nutritive fluid I may be permitted to state that I became almost convinced that the death of cells under these circumstances is attended by the development of micro organisms My observations on this point, however, were not absolutely satisfactory It is almost impossible to exclude all sources of error and I do not wish to be understood as having stated this to be a certain fact Most of these experiments were made with a Zeiss 1–25 inch lens Before leaving this part of our discourse I must say that all later observers seem to agree on the fact that the nucleus is the essential part of a cell, and that the reproductive function at least emanates from it The other functions of the nucleus, if there be any, are unknown The fact, however, that reproduction starts and is principally carried on by the nucleus, sufficiently proves that the nucleus is the most important part of the cell As long as the idea that a nucleus which is not surrounded by protoplasm or cell-substance does not exist as a living entity controls the mind, it will be very hard to grasp the weight and bearing of the above observations

Histologists who are accustomed to work almost exclusively with tissues of higher organisms never think of a living nucleus without protoplasm, even as a possibility After a time, when the fact that there are numerous organisms which are homologous to free nuclei shall have been recognized and corroborated, the supposition that the nucleus is, genetically speaking, the older and most essential part of a cell will seem as evident as it has seemed heretofore that the cell substance was the important part of the cell This latter opinion is based upon the hypothesis that the nucleus is only "condensed or differentiated protoplasm" It supposes that protoplasm is the basis of all life But we know of many organisms, for instance, schizomycetes or micrococci, whose chemical and morphological appearances in no way correspond to those of protoplasm We know also that the nuclei of cells, as well as the free living nuclei, are not protoplasm The protoplasm theory must therefore be given up, it is imperfect and is not called for by the facts I should not wonder if in a few years it will appear strange how such an error as the slighting of the nucleus in favor of the cell substance, making the latter the more important, and giving the nucleus only a secondary position, could have occurred The greatest living investigators, men who usually proceed in a most logical and scientific way, have fallen into this prejudice We know of no example of a cell in the animal kingdom that neither has nor ever had a nucleus The so called cell substance, however, is not really so constant a factor, we find it in the most varying conditions We do not know that any cell without a nucleus is capable of division or multiplication, but I have seen the division of the living naked nucleus These facts all tend to demonstrate the primary and essential importance of the nucleus in contradistinction to the cell-substance The function or use of the latter is unknown Possibly it serves the purposes of nutrition in the beginning and is afterwards used for a great variety of purposes, the nucleus always being the essential part so long as it lives

No one will dare to deny that the great progress made in the natural sciences in modern times is chiefly due to the recognition of the great principle of evolution This principle itself was established most thoroughly by the two disciplines called comparative anatomy and embryology It is very evident that the main progress we have made towards a scientific understanding of organic life, has been reached not by study only of the adult or perfect stages of our objects, but by the observations made on the different stages of the growing organism during its development Gegenbaur says "Thus ontogeny and comparative anatomy appear as the scientific basis of human anatomy" The latter discipline has been placed upon a more scientific basis, since the introduction of the onto and phylo genetic methods of investigation These methods, I deem, are the ones which should be employed in all instances where a question arises concerning the position of any given organism in the pedigree of life

Mr Ernst Haeckel himself has fallen into a grave error here, which undoubtedly will cause the toppling over of his entire structure, grand and wonderful as he has built it Mr Haeckel is the author of the biogenetic fundamental law This law, generally speaking, says Embryology (ontogenesis) is a condensed and abbreviated repetition of phylogenesis, or the development of the race We may accept this thesis for the present, reserving the right to modify or amend it in future Mr Haeckel started his tree of life upon the foundation of protoplasm, from this he jumped to what he calls monera These organisms are cytodes without a nucleus, merely small pieces of cell substance or protoplasm Next he allows a nucleus to be differentiated out of this protoplasm These, then, are his *cells* In order to decide the question where the cells belong in the scale, Mr Haeckel should have used the methods above mentioned, and under the guidance of his biogenetic law he might have undoubtedly reached the true conclusion

This now brings me to the main point of this essay In order to decide what the cell is, let us see whereto the ontogenetic method will lead us No sane person will claim that a cell must needs be the lowest living entity If, therefore, we can observe the ontogenesis of higher organisms, why may we not try to study the development of a cell? I have faithfully tried this method with all the technical appurtenances, aids and ingenuity at my disposal I have only partially succeeded, but what I have seen is very encouraging I repeatedly saw a naked living nucleus, while under observation, develop or attract unto its surface (out of the water or nutritive fluid in which the nucleus was examined) small particles of substance which seem to me to correspond exactly in optical appearances to what is usually called cell substance or protoplasm The comparative method, when applied to the examination of free nuclei and cells, yielded an almost perfect result As I stated above, I saw all the stages of living organisms which naturally range between a naked nucleus and one entirely covered by cell-substance This observation is readily made and can be corroborated by any careful microscopist who is accustomed to work with high powers

Placing the results thus obtained together with the beautiful work done by Fleming, Rabl, Arnold, Strassburger, Kupfer and others on karyokinesis, the conclusion which seems absolutely unavoidable is that the nucleus existed before the so called cell and before protoplasm Protoplasm or cell substance is a product of differentiation of the nucleus

I extended my investigations one step farther after I had determined the primary importance of the nucleus I attempted to analyze the nucleus itself by the methods of development and comparison As above stated, I plainly saw that within the nucleus there existed active moving bodies of definite forms Their movements remind the observer of the movements of the smallest micrococci and bacteria The refraction of light and their chemical reactions also correspond closely to those of these lowest of all known organisms As above stated, these bodies sometimes leave the nuclei through pores in the nuclear membrane, and others seem to enter into the same places This, together with the observation, which is not yet well enough established to be convincing, that a cell or its nucleus, when left to die in a sterilized nutrient fluid, will set free micro organisms, would seem to indicate the hypothesis that the nucleus is a conglomeration of micrococci or a *syncoccium* This, however, I desire to have understood is by no means a conclusion which deserves any more notice than a preliminary hypothesis, based as it is on observations which I consider entirely too doubtful for a scientific result

Before ending my essay I may take the liberty of setting up the following theses as the result of my observations and reflections

Theses

I The hypothesis that protoplasm is the basis of all life is untrue

II The hypothesis that cells are the result of the differentiation of protoplasm is untenable

III The hypothesis that the so called cytodes, or cells without nuclei, are phylogenetically the ancestors of cells (with nuclei) is false

IV The nucleus is phylogenetically the progenitor of the cell

V A cell is an organism which is developed by differentiation and growth from a nucleus

VI The process of karyokinesis is a part of the ontogeny of cells

Hypothesis

The lowest known stages of the phylogenetic tree of organic beings are

I Micro organisms
II Free nuclei = synococcium?
III Cells

In order to show the usefulness of my hypothesis, let us look for a moment at the origin of hereditary disease It is a fact that a parent will transfer to its offspring many of its peculiarities One of these is sickness We know that tuberculosis, commonly called consumption, is often inherited We know that this disease is caused by the development of a micro organism, which is called bacillus tuberculosis

It has been necessary to accept the hypothesis that the parent only transmits a peculiar diathesis to the offspring, which makes it more susceptible to the micro-organism But, as all practitioners of medicine know, this hypothesis is not tenable in all cases There are cases known where children were separated from their parents soon after birth—say seven orphans were adopted by seven different families, and placed in the most varying external relations, still not one of them lived to be 28 years of age Is it reasonable to believe that a tubercle bacillus found its way into each of their lungs and there set up its work of destruction? It seems to me that an explanation in every way more plausible can be derived from the supposition that the egg cell of the mother or the spermatozoon of the father bore within them the taint, perhaps the veritable bacillus itself, or the homologon of a spore as one of the component parts of these elements

CONCERNING VAGINAL INJECTIONS[1]

BY W THORNTON PARKER, M D (MUNICH),

OF NEWPORT R I

Almost every work upon gynecology acknowledges the importance of vaginal injections in the treatment of disease of the pelvic viscera, and at present it seems to be the general opinion that these injections must be received by the patient while lying on her back with elevated hips, if good results are to be expected

The uselessness of the small stream attainable from almost every syringe is well known, and while Scanzoni has taught for so many years the necessity for copious injections, he has never supplied the apparatus If we consult our works on gynecology, we will be surprised to discover the numerous syringes and appliances offered for vaginal injections

So miserable, useless and even dangerous are the syringes supplied that Dr Emmet has concluded that the only syringe worth using is the "Fountain," and "that no patient can use vaginal injections efficiently herself, but must have them administered by another " For *this* vaginal injection the services of a nurse or servant must be employed, or else elaborate preparation of bed and bed clothing, and the many details connected with the operation must be carefully carried out It is very interesting to consider the minute details and the complicated methods recommended by such writers as Thomas and Emmet, who are such giants in the practical operations which have revolutionized gynecological surgery A collection of the descriptions for preparing patient and bed for recumbent vaginal injections is really astonishing, and in many cases one is forced to either devote a good hour to unravel the puzzle, or else to conclude that a patient once subjected to such fussy preparation *might* be willing to receive *one* such injection, but hardly a second Indeed, to subject a nervous patient to such elaborate preparations is a miserable imposition, and is undoubtedly very often sufficient to discourage further interest in the progress of the treatment of the case Such discouragement has indeed often put a positive stop to all further attempt at a case, and the woman of ordinary modesty feels outraged by the exposure necessary for the injection, which disturbs her much more than mounting the elaborate brass mounted table so common in the offices of our amateur gynecologists

The use of the vaginal syringe should be accomplished with as little annoyance to the patient as the simple operation of washing her hands or her face, and when this can be demonstrated then, and not till then, will the bidet find its way for daily use in countless homes, not as a preventative against conception, but as a precaution against disease Thomas, however, opposes the sweeping assertion of Emmet, that vaginal injections received from a bidet are useless, and is willing to allow that some good can be derived from such injections, but in a limited, very limited, degree

When we read on further in Dr Thomas's work, and find that he recommends the common Davidson syringe, one cannot be surprised that his doubts are freely expressed as to the efficacy of vaginal injection He has freely quoted Scanzoni in urging copious vaginal injections, and yet he must know that at present the average so called female syringe is utterly unable to supply a sufficiently copious stream to be of any use whatever The works of American gynecologists are all in error on this important topic, but if we consult the writings of Barnes and Edis we shall find that vaginal injections from the bidet, or even the common basin, are highly recommended and are frequently successful, because the syringes sold in England are mostly the admirable ones of Higginson, and not the useless apparatus found for sale in our drug shops Few writers on gynecology have presented such a useful and practical book as that of Edis, on "Diseases of Women," and some of his remarks are so excellent that I take the liberty to quote them "Syringes made of India-rubber are the most suitable, pewter or glass should never be used Higginson's syringe is one of the most convenient form The vaginal tube should be adjusted so as to lessen the force with which the fluid is injected, and prevent the possibility of the nozzle being inserted into the cervix Instances of severe uterine colic, intense agony, peritonitis, and even death, from the employment of vaginal injections, have been recorded[1] In some cases this may possibly be explained by the tube being inserted into the patulous cervex of a retroverted uterus We cannot therefore be too careful in explaining to the patient how to use the syringe properly " Barnes asserts that "injections fail because they do not touch the main seat of the disorder, which in the majority of cases is in the uterus itself, but although they fail to cure, they may be useful as far as they go " He, however, recommends vaginal injections with the Higginson syringe, and considers the bidet the useful vessel that it is

In 1879 I devised a vaginal syringe, made by Tiemann & Co, of New York which has since been greatly improved The bulbs for this syringe were manufactured at first in Paris, making the syringe very expensive, but lately Messrs Tiemann & Co have manufactured these bulbs in New York, and it is now possible to obtain the best vaginal and rectal syringe which I know of, not excepting the excellent English Higginson, from them This syringe is made entirely of rubber, and the vaginal and rectal tubes are perfectly flexible There is no terminal orifice, but the sides are perforated with velvet eyes for a distance of nearly two inches from the end These rubber syringe points do not lacerate the mucous membrane nor produce the injury so often caused by the hard metallic tubes The bulb and tube are large and

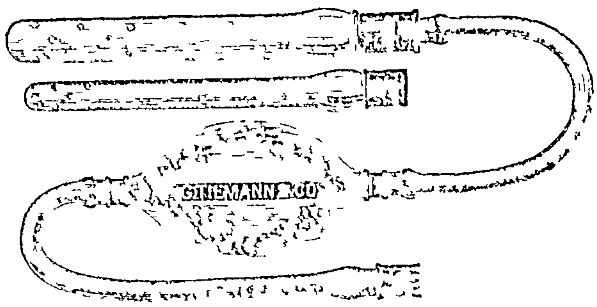
[1] Read before the Newport Medical Society on October 7 1885

[2] Quoted by Thomas Diseases of Women " p 74

[1] A death from the use of a Davidson s syringe is reported in the Gynecological Journal 1872, p 340 et seq

[2] New York Med Record July 5 1879



afford a copious supply of water For use in the recumbent position the vaginal douche pan invented by Dr Baker, or the Reynolds siphon bed pan manufactured by Otis Clapp & Son, are to be recommended, but the necessity for the use of the bed pans referred to is only when the patient is too feeble to administer the injections herself

With the bidet and the syringe which I have already described, a safe and useful vaginal injection can be obtained[1] The patient can make herself very comfortable on the bidet, and the syringe is so constructed that very little effort is required to empty the bulb, and pour out into the vagina a copious supply of water, estimated as being many times greater than that obtained from any other syringe at present in existence The dangers of uterine colic and other accidents while using this syringe and the bidet are reduced to the minimum A thorough washing of the vaginal walls is easily accomplished, and a large bidet allows a much greater supply of water, and is consequently a cleaner apparatus than can be possible from any bed pan or fountain syringe It is worth something for the patient to be able to arrange for and to use the bidet without trouble and innumerable preparations It should be used just before stepping into bed I direct my patients to fill the bidet as full as possible with water from 100° to 110° F in temperature, when ready for use The patient should have the legs covered with warm stockings, the feet encased in warm slippers, and if weak a warm wrapper can be thrown over the shoulders The injection should be continued for at least ten minutes The ingredients to be added to the hot water should be carefully mixed with the water before using After the injection the parts should be well dried with a soft towel, a suppository introduced and a napkin applied immediately upon entering the bed For the treatment of ordinary leucorrhœa I direct that the hollow vaginal suppositories of Dr Chas I Mitchell, of Philadelphia, and a formula devised by myself, consisting of sulpho carbolate of zinc, grs x, and sulphate of morphia grs ss, be used, or else the suppositories of boro glyceride made for me by Messrs Theodore Metcalf & Co, of Boston In the *New York Medical Record*, Sept 24, 1882, the *American Journ of Obstetrics*, Feb, 1884, the *Philadelphia Med Times*, Sept 20, 1884, and the *Virginia Medical Monthly*, August, 1885, I have called attention to the valuable properties of boro glyceride, especially in gynecological practice For those of my readers who are not acquainted with boro glyceride I would quote the following from the *British Medical Journal* "Boro glyceride is a body of definite chemical composition ($C_3H_5BO_3$), which forms a definite hydrate with a large quantity of boiling water, and is not, we are informed, decomposed when diluted in the proportion useful in surgery—one part to twenty or thirty parts of water Such a solution is inodorous, has a slight saltish taste, and is quite unirritating to a wounded surface Under its use wounds of all kinds do extremely well, and heal fully as rapidly as under carbolic acid dressings over which boroglyceride has the advantage that it does not irritate the wound or the surrounding skin, and that it is, so far as is known, entirely innocuous when applied to a wounded surface" Messrs Theodore Metcalf & Co, of Boston, have at my suggestion made vaginal and rectal suppositories of boro glyceride in combination with gelatin and pencils of the same for intrauterine and other uses These contain twenty-five per cent of boro glyceride The suppositories are of three sizes, Nos 1, 2 and 3 No 1, the smallest, is a useful suppository in various rectal disorders, particularly in hemorrhoids and pruritus ani They are also useful in the treatment of thread worms No 2 is of medium size, for either vagina or rectum, and No 3 is indicated where a larger amount of boroglyceride is required in cases of chronic leucorrhœa, vaginitis or of uterine diseases in general The largest suppositories should not be used more than three nights in succession, and experience has taught me that the best results are obtained by using them every other night Boro glyceride is an excellent application for a lacerated cervix, spread thickly on the diseased surface It can also be spread on absorbent cotton, and introduced and applied in that manner The cleanliness and gentleness of this remedy, and the steady improvement resulting from the use of boro glyceride, will be very satisfactory to both patient and physician

Dr Storer considers that four general indications exist for vaginal injections 1 As a lavement for cleansing purposes 2 For the purpose of producing a deep seated effect for relieving chronic congestions 3 Where an exosmotic effect is desired, as in the use of saline and other solutions 4 Where a local effect is desired, corresponding with gargling for the throat, etc In the latter class of cases the recumbent position might be more advisable He thinks that vaginal injections are unquestionably too often prescribed, and that physicians are reckless in directing ingredients for vaginal injections that are of the most unsuitable kind, and often productive of lasting injury Sometimes even dangerous ingredients are used, creating instead of alleviating disease. Such injections are sometimes followed by a more serious disease than they were at first intended to relieve. The same discretion should be used in prescribing vaginal injections that one employs in treating the mucous membrane of the eye or fauces. Every gynecologist must have witnessed the deplorable effects resulting in almost ruined vaginal walls from too severe injections of such substances as alum, tannic acid, etc. With the most ordinary skill on the part of the medical attendant, the syringe which we recommend ought to be a safe one. It is well, however, to remember that serious injury has resulted from neglect to empty the air from the tube before inserting into the vagina. Care should be taken that no air enter the bulb or tube while filling the syringe. By using a bidet this accident is more readily avoided if plenty of water be used, but with an ordinary hand basin it is of frequent occurrence.

---

[1] The bidet is a triangular stool about sixteen inches high containing a porcelain basin which can be easily lifted out and cleaned The stool is peddle shaped the broad end for the support of the buttocks and narrow anteriorly It can be obtained at many of the house furnishing goods stores Incidentally it may be well to mention the fact that the bidet is useful for the treatment of rectal diseases of both sexes For bathing hemorrhoids or prolapsed ani it is certainly preferable to the pans so generally recommended A modest prejudice exists against the bidet many ladies disliking to use one since it is so well known that French women use them to prevent conception

Many syringes are so constructed that a pint or more of water answers for the entire "sitting," being used over and over again, becoming filthier and filthier each moment. Such machines have little to recommend them. A copious water supply and a copious stream are the most desirable features in a good vaginal injection, and a syringe which cannot accomplish this is simply worthless. Cheap syringes are commonly offered for sale because they are cheap. For a good vaginal syringe a fair price must be paid. In drawing attention to the dangers from careless vaginal injections it may be well incidentally to note the recklessness with which some medical men recommend intra-uterine injections. This is the more inexcusable, since so many general practitioners practice gynecology to a considerable extent. Intra-uterine injections are seldom justifiable, and then only when they can be employed by a safe instrument acting more or less on the principle of the double canula. For the vaginal injection with the syringe we recommend, the best possible ingredients are boro glyceride in solution, borax, and even common salt in suitable proportions. Much of the benefit derived by women from sea bathing, aside from the general constitutional tonic effect of sea side air, and salt-water baths, is the fact that the sea water does actually enter the vagina during the usual exercise of bathing, and exerts thereby a cleansing, healing effect upon the vaginal walls. While the possibility of such entrance of salt water has been denied by some, on the ground that the walls are too closely approximated to admit any water, the fact remains the same that water actually does enter, and that inquiries made have proved this beyond question, not only in the case of multiparæ, but of others, and even virgins. The closure of the vaginal walls is not like that of the closure of sphincter ani. Besides these preparations there are others which can be used in greater or less strength, according to indications. The large tube will be found often too large for unmarried women, and for such cases the rectal tube can be used, but generally speaking the larger vaginal tube is suitable where injections are found to be necessary. The use of the syringe cannot alone cure diseased vaginal walls, and the atomizer and other appliances must play their part, not to speak of the surgery necessary for the uterus and the special treatment needed in all uterine cases. In vaginal injections properly administered we have an invaluable aid in the treatment of many of the diseases of women, and a guard against the attacks of diseases to which woman is so liable.

In conclusion, the physician should be careful to advise against the prolonged use of vaginal injections during pregnancy, and also to caution patients against using injections of any kind during the menstrual period. To many these warnings may seem superfluous, but the physician of any experience must have seen much harm resulting from ignorance of these very simple laws, in medical attendants.

Newport, October 7, 1885.

SIMPLICITY AND ADAPTABILITY IN THE TREATMENT OF FRACTURES

BY GEO. N. MONETTE, M.D.,

OF NEW ORLEANS, LA.

In a former issue of THE JOURNAL Dr. John B. Roberts, of Philadelphia, made an especial mention and advocacy of simplicity, as also strict anatomical appreciation of surgical appliances, in the treatment of fractures. Text books, too often, bias the practitioner in his isolated field of labor, and he is often denied treatment of cases owing to his not being supplied with orthodox paraphernalia requisite for certain cases. Let each one, so called upon for surgical advice, only exercise his inherent ingenuity, and then make such an appliance as common sense and the anatomico surgical indication would point to.

The preservation of the integrity of the limb, both as appertaining to bony and muscular and integumentary tissues, must of necessity engage the attention of the attendant. Having a compound fracture, the appliance must be adapted with especial reference to immobility for the bone, as a comfortable exit at the seat of the laceration for all suppurative discharges, guarding cautiously against too great compression of the sympathetically inflamed tissue. This must not be actuated by any routine, as laid down in the books. I have been able to treat and control successfully all of my cases of fracture upon the impulsive plan, not by fixed laws relative to authorities, but as the case and common sense would indicate, save that, with Liston's long lateral splint for fracture of femur. The use of Liston's straight lateral splint for fractures of the femur, is confined by the indications for its use. In my experience, I have had one case of fracture of the femur which resulted with overlapping extremities, not through any fault of the splint, nor inaptitude on my part, but through a meddlesome daughter, who slackened the perineal strap after my morning (*daily*) visit, when I had at each visit drawn the strap taut. Her interference caused some irregularity, I had no recourse, hence my case was not a success.

In compound comminuted fractures the utmost care in the application of dressings must be exercised, and as to routine bandaging, the same must be rigidly dispensed with. I have treated such cases without a bandage, and have also departed from the prescribed course for such cases Each case develops features of its own, which necessitates a certain method of utilizing appliances, and the identical repetition as to seat of fracture in another case would reveal diverse phenomena Hence it becomes the imperative duty of the surgeon to devise his appliances suitable to his needs, exercising his individual ingenuity of adaptation, and with especial appreciation of the anatomy of the part involved in its mechanico mobility, normally, and after union of the fracture

As regards fracture of the femur in children, suppose we have a case in an infant six or eighteen months old What can be more cruel than a straight splint? My plan for treating these cases is to put them in a flexed position, similar to the sitting posture, and with extension of the anterior and posterior splints about the waist, and held by a band, and the lower extremities of the splints carried to or beyond the toes By this method there is the most rigid immobility of the limb, and with comfort to all parts enveloped by the bandages My first application of this form of splint was in the spring of 1868, and whenever a suitable case presents I utilize the identical form of splints, anterior and posterior, in conformity to a sitting posture

Each day develops some ingenious contrivance for every form of fracture, but it is incumbent upon the surgeon to dispense with inventions to a great extent and utilize his ingenuity conformably with indications of his particular case, and there will be neither fault nor deformity

Fractures of the clavicle offer some discouraging results, as the movements of the thorax (as in lying down) are prone to militate against permanent adjustment of any sort of dressing It seems to me that a little more simplicity is requisite, for instance, simply binding the arm to the thorax by a bandage In fractures of the clavicle in infants and very young children, the former particularly, I have pinned the sleeve of the arm of the fractured side to the dress anteriorly, or about the median line, across the chest Such treatment has resulted successfully, and with no more prominence of a callus than from the routine Fox apparatus, or that of any other specialist in surgical appliances This confinement is readily tolerated by children, and a little pain causes them to bear it patiently The nature of the fracture in children tends to confirm my method With diminished ossific development, the fracture is not distinct, hence the reapposition of the splintered fragments is readily accomplished, solidification takes place promptly, and immobility is attained sooner than in similar fractures in adults

I need not mention other fractures, as simplicity can be more readily appreciated in those enumerated than in those not mentioned, as the form of treatment is absolutely indicated Recovery and restitution are much more speedy and satisfactory, and at the same time careful inspection can be made by the attendant at opportune periods, without fear of compromising the progress of bony union

285 Camp Street

MEDICAL PROGRESS

DISINFECTANTS —The Committee on Disinfectants of the American Public Health Association conclude their report as follows The experimental evidence recorded in these reports seems to justify the following conclusions The most useful agents for the destruction of spore containing infectious materials are 1 Fire Complete destruction by burning 2 Steam under pressure 110° C (230° Fahr) for ten minutes 3 Boiling in water for one hour [1] 4 Chloride of lime A 4 per cent solution 5 Mercuric chloride A solution of 1 500

For the destruction of infectious material which owes its infecting power to the presence of micro-organisms not containing spores, the Committee recommend 1 Fire Complete destruction by burning 2 Boiling in water half an hour 3 Dry heat 110° C (230° Fahr) for two hours 4 Chloride of lime [3] 1 to 4 per cent solution 5 Solution of chlorinated soda [4] 5 to 20 per cent solution 6 Mercuric chloride A solution of 1 1000 to 1 4000 7 Sulphur dioxide Exposure for twelve hours to an atmosphere containing at least 4 volumes per cent of this gas, preferably in presence of moisture [5] 8 Carbolic acid 2 to 5 per cent solution 9 Sulphate of copper 2 to 5 per cent solution 10 Chloride of zinc 4 to 10 per cent solution

The Committee would make the following recommendations with reference to the practical application of these agents for disinfecting purposes

For Excreta —(*a*) In the sick-room For spore-containing material 1 Chloride of lime in solution, 4 per cent 2 Mercuric chloride in solution, 1 to 500 [6] In the absence of spores, 3 Carbolic acid in solution, 5 per cent 4 Sulphate of copper in solution, 5 per cent 5 Chloride of zinc in solution, 10 per cent (*b*) In privy vaults Mercuric chloride in solution 1 500 (*c*) For the disinfection and deodorization of the surface of masses of organic material in privy vaults, etc Chloride of lime in powder [6]

For Clothing, Bedding, etc —(*a*) Soiled under-clothing, bed linen, etc 1 Destruction by fire if of little value 2 Boiling for at least half an hour 3 Immersion in a solution of mercuric chloride of the strength of 1 2000 for four hours [8] 4 Immersion in a 2 per cent solution of carbolic acid for four hours (*b*) Outer garments of wool or silk, and similar articles, which would be injured by immersion in boiling water or in a disinfecting solution 1 Exposure to dry heat at a temperature of 110° C (230° F) for two hours 2 Fumigation with sulphurous acid gas for at least twelve hours, the clothing being freely exposed, and the gas present in the disinfection chamber in the proportion of four volumes per cent (*c*) Mattresses and blankets soiled by the discharges of the sick 1 Destruction by fire 2 Exposure to superheated steam—twenty five pounds pressure—for one hour (Mattresses to have the cover removed or freely opened) 3 Immersion in boiling water for one hour 4 Immersion in the blue solution (mercuric chloride and sulphate of copper), two fluid ounces to the gallon of water

---

[1] This temperature does not destroy the spores of *B subtilis* in the time mentioned but is effective for the destruction of the spores of the anthrax bacillus and of all known pathogenic organisms

Should contain at least 25 per cent of available chlorine

[3] Should contain at least 3 per cent of available chlorine

[4] This will require the combustion of between three and four pounds of sulphur for every 1 000 cubic feet of air space

The addition of an equal quantity of potassium permanganate as a deodorant and to give color to the solution is to be recommended (*Standard Solution No* 2)

[6] A concentrated solution containing four ounces of mercuric chloride and one pound of cupric sulphate to the gallon of water is recommended as *Standard Solution No* 3 Eight ounces of this solution to the gallon of water will give dilute solution for the disinfection of excreta containing about 1 500 mercuric chloride and 1 125 of cupric sulphate

[7] For this purpose the chloride of lime may be diluted with plaster of Paris or with c[illegible]an well dried sand in the proportion of one part to nine

[8] The blue solution containing sulphate o[illegible] two ounces o[illegible] the con[illegible] for this purpose

For Furniture and Articles of Wood, Leather, and Porcelain[1]—Washing, several times repeated, with 1 Solution of mercuric chloride, 1 1000 (The blue solution, four ounces to the gallon of water, may be used) 2 Solution of chloride of lime, 1 per cent 3 Solution of carbolic acid, 2 per cent

For the Person —The hands and general surface of the body of attendants, of the sick, and of convalescents at the time of their discharge from hospital 1 Solution of chlorinated soda diluted with nine parts of water (1 10) 2 Carbolic acid, 2 per cent solution 3 Mercuric chloride, 1 1000, recommended only for the hands, or for washing away infectious material from a limited area, not as a bath for the entire surface of the body

For the Dead —Envelop the body in a sheet thoroughly saturated with 1 Chloride of lime in solution, 4 per cent 2 Mercuric chloride in solution, 1 500 3 Carbolic acid in solution, 5 per cent

For the Sick Room and Hospital Wards —(*a*) While occupied, wash all surfaces with 1 Mercuric chloride in solution, 1 1000 (the blue solution containing sulphate of copper may be used) 2 Chloride of lime in solution, 1 per cent 3 Carbolic acid in solution, 2 per cent (*b*) When vacated Fumigate with sulphur dioxide for twelve hours, burning three pounds of sulphur for every 1,000 cubic feet of air space in the room, then wash all surfaces with one of the above mentioned disinfecting solutions, and afterward with soap and hot water, finally throw open doors and windows and ventilate freely

For Merchandise and the Mails[2]—The disinfection of merchandise and of the mails will only be required under exceptional circumstances, free aeration will usually be sufficient If disinfection seems necessary, fumigation with sulphur dioxide, as recommended for woolen clothing, etc, will be the only practicable method of accomplishing it

For Rags —(*a*) Rags which have been used for wiping away infectious discharges should at once be burned (*b*) Rags collected for papermakers during the prevalence of an epidemic should be disinfected before they are compressed in bales by 1 Exposure to superheated steam (twenty-five pounds pressure) for ten minutes 2 Immersion in boiling water for half an hour (*c*) Rags in bales can only be disinfected by injecting superheated steam (fifty pounds pressure) into the interior of the bale The apparatus used must insure the penetration of the steam to every portion of the bale

For Ships —(*a*) Infected ships at sea should be washed in every accessible place, and especially the localities occupied by the sick, with 1 Solution of mercuric chloride, 1 100 (the blue solution heretofore recommended may be used) 2 Solution of chloride of lime, 1 per cent 3 Solution of carbolic acid, 2 per cent The bilge should be disinfected by the *liberal* use of a strong solution of mercuric chloride (the concentrated solution—"blue solution" of this salt with cupric sulphate may be used) (*b*) Upon arrival at a quarantine station an infected ship should at once be fumigated with sulphurous acid gas, using three pounds of sulphur to every 1,000 cubic feet of air space, the cargo should then be discharged on lighters, a liberal supply of the concentrated solution of mercuric chloride (four ounces to the gallon) should be thrown into the bilge and at the end of twenty four hours the bilge-water should be pumped out and replaced with *pure* sea-water, this should be repeated A second fumigation after the removal of the cargo is to be recommended, all accessible surfaces should be washed with one of the disinfecting solutions heretofore recommended, and subsequently with soap and hot water —*Report of the Committee on Disinfectants of the Amer Pub Health Association*

THE PREVENTION OF MAMMARY ABSCESS —DR A W EDIS, in a note on this subject, says It being believed that friction of any kind, in the large majority of cases, rather tended to produce than prevent mammary abscess it was long since discarded The application of a long strip of belladonna plaster, sixteen or eighteen inches long and six or eight inches deep, with round apertures, so as to leave the nipples free, tightly across the chest, the breasts being brought well up towards the median line, for many years was the only resource adopted, beyond careful regulation of the diet, abstention from fluids, gentle purgation, etc This method never failed, but it was often found that the smell of the belladonna produced so much nausea in delicate patients as to preclude the employment of it Thinking that, in all probability, the pressure exerted, contributed greatly to the advantage derived, I was induced to rely upon a few turns of a rib bandage, or the application of a thin towel or diaper across the chest, the breasts being brought well towards the sternum Since adopting this method, I have never known it fail Not a single instance of mammary abscess has occurred in a long series of cases, extending over several years The only precaution requisite is to apply the pressure on the second day following parturition, before the breasts begin to fill, and to see that the whole of the glands are included

It is well to elevate the shoulders somewhat more than usual, and not to allow the bed cloths to cover the upper part of the chest, the sheet alone sufficing to prevent any risk of chill Restriction as to the amount of fluid, for the first few days, and attention to the bowels, are all that is requisite to ensure success Some little inconvenience, a feeling of tightness, or burning pain, is often experienced, but if the pressure be maintained no harm results, and within the course of a few days, the turgescence subsides, and the difficulty is at an end In order to keep the bandage or towel from slipping down, a shoulder strap from back to front, or merely pinning the bandage to the night dress, suffices Where the secretion of milk seems to be unusually abundant, a mixture of bromide and iodide of potassium may be prescribed with benefit In only a few instances has it been found requisite to draw off a small quantity of milk, by means of a breast pump or exhausted soda water bottle, and this only once or twice

---

[1] For articles of metal use Solution No 3

[2] In order to secure penetration of the envelope by the sulphur dioxide all mail matter should be perforated by a cutting stamp before fumigating

I venture to think these remarks may prove of value to many, as I not unfrequently see instances of mammary abscess brought on, I verily believe, by the old fashioned method of rubbing and irritating the breasts —*British Medical Journal*, Nov 7, 1885

HYPNONE AS A HYPNOTIC —The fanciful name hypnone has been applied to methylphenylacetone At the request of M Dujardin Beaumetz, who insists that it should be used only in cases of sleeplessness from over excitement of the brain, and not where there is pain, M Pierre Vigier (*Gaz hebdom de Med et de Chir*) has experimented with regard to its administration The amount necessary to produce sleep varies from four to ten drops, which should be taken all at once, for divided doses do not succeed The drug is scarcely soluble in water, and but slightly soluble in glycerine, but dissolves readily in alcohol A syrup may be made in the following proportions

Hypnone	1 drop,
Ninety per cent alcohol	15 grains,
Syrup of orange flowers	75 "
Syrup of cherry laurel	14 "

Let the drop of hypnone fall into the alcohol, add the syrups, and keep in a tightly-stopped bottle In like manner an elixir may be made of the following ingredients

Hypnone		1 drop,
Sixty per cent alcohol, Syrup of Mint	each	45 grains

The taste of these preparations is said to be very bearable The drug itself has a very hot taste, and its odor reminds one of essence of bitter almonds, with a suggestion of wintergreen —*New York Medical Journal*, Dec 19, 1885

NERVE SUTURE, WITH IMMEDIATE RESTORATION OF FUNCTION —One of the most remarkable results of the suture of a nerve ever reported is given by SURMAY, in the *Archives Gen de Medecine*, for Oct 1885 The case was that of a man who had received a cut above the wrist, resulting in abolition of the function of the median nerve For some time no attempt had been made to correct the defect Then electricity was tried without result Six months after the accident, Surmay resected about three quarters of an inch of the nerve, and joined the cut ends with a fine carbolized catgut thread, which had been ingeniously inserted before the intermediate portion was cut out The function of the nerve was reestablished within twenty four hours! The parts which had before been affected—the second phalanx of the thumb and the two terminal phalanges of the index and middle fingers—were found to have wholly recovered their general and tactile sensibility, while the sensibility to pain and temperature had returned in the thumb and in the upper half of the phalanges of the other fingers involved Complete restoration followed after several months

This remarkable case furnishes a strong support to operative interference in other cases than those in which loss of function results from traumatic division of a nerve, for in this one the nerve was not found divided, but the part under the wound was occupied by an enlargement which was formed by pure hypertrophy of the neurilemma It is always surprising that the cicatricial changes which must take place in or immediately adjacent to, a resected nerve, should have so little effect in disturbing the result of the operation In the case mentioned, it seems to have had some disturbing influence, although this passed off with time Further, this case is interesting as raising questions in physiology which will bear close study, namely, as to the reinstatement of one part of the function of a nerve while another remains in abeyance, as well as in regard to the relation of the different forms of sensation, which are commonly divided into common sensation or sensation of pain, and the tactile sense, which includes appreciation of changes in temperature As Surmay's case seems to have been studied with great care, and to present many of the conditions of scientific accuracy, it may contribute materially to our knowledge of the physiology of the nerves —*Medical News*, Dec 19, 1885

GRADUATED BATHS IN TYPHOID FEVER —DR J PEDLOW, in a note on this subject, says During my last year in India I used a graduated bath in all cases, as a rule, where the temperature reached 102 5° at 3 o'clock in the afternoon, and was rising I had a special bath made for this purpose, a little over five feet long, and rather shallow The patient, rolled in a thick blanket, was lifted into it, and the head rested on a pillow in the bath The water was usually at a temperature of 86° Fahr , instead of reducing it, it was gradually brought up to 92° and 93° By this means, when the patient's temperature remained high, I was able to keep them in the bath for an hour or more without much feeling of chilliness The tendency to the latter was also often obviated by keeping the hands in an India rubber bag filled with hot water The temperature was frequently taken in the mouth Many patients in whom, owing to delirium, this could not be noted before immersion, became quite tranquil in the bath, and the observation was easily made In this way, I used it in seven very severe cases in the summer and autumn of 1883, in Bangalore, at the infantry station hospital, of these, six recovered In the case which died, it was only used twice, at a time when the bowel, as indicated by the stools, was in a gangrenous condition, and when the case was considered hopeless When we look at the very early period at which cerebral and intestinal lesions appear in severe cases of Indian enteric, it becomes the more imperative that the bath should be early resorted to, and systematically continued, morning and afternoon, as long as the temperature runs high; a marked fall of two or more degrees will usually occur three-quarters of an hour in a bath of about 90° F. In other respects, improvement is noted; the dry parched lips become moist and softer, delirium disappears and the intellect clears up. I have no doubt that if the bath treatment, as laid down in most text books, or in the way I have briefly noted, were more frequently resorted to, under the careful personal supervision of the medical officer in charge of the case, the mortality of this fever would be very much reduced in India.—*Brit. Med. Jour.*, Nov. 28, 1885.

The Physiology of Hepatic Colic.—N. P. Simanowsky, (*Zeit. Klin. Med.*, Band V.), wishing to clear up the physiology of hepatic colic, has recently undertaken a series of experiments upon dogs. He first established a biliary fistula, and, afterward, submitted the gall bladder to different forms of irritation. As a result of his experiments, the following conclusions were reached:

1. The introduction of electrodes or any other foreign body into the gall-bladder produces violent pain.
2. When the electrodes are introduced or withdrawn, pain, similar to that caused by spasmodic contraction of the walls of the gall bladder is produced.
3. The pulsations of the heart are increased in frequency under the influence of feeble electric currents. They are diminished by strong currents, and the cardiac rhythm is disturbed.
4. When the electrical stimulation is maintained for a considerable period, the cardiac actively diminishes. Under the same conditions the same effect is observed with feeble currents.
5. Electrical excitation increases the frequency of respiration (twenty to seventy respirations per minute). Strong excitation causes a momentary arrest of respirations.
6. The rectal temperature is elevated during excitation. There is no relation between this effect and violent movements on the part of the animal.
7. The temperature of the skin, taken at symmetrical points presents great variation under such excitation of the gall-bladder, being frequently elevated on one side and depressed on the other.
8. At the termination of such experiments, paresis of the posterior limbs was not infrequently observed. In some cases this condition persisted for several months.
9. Excitation of the gall bladder frequently produced vomiting.
10. Excitation always produced increased blood pressure, provided that the vagus had not been previously divided in the neck.—*Revue des Sciences Medicale*, July, 1885.

Strychnia in Nervous Disease.—In an article on this subject, in the *American Journal of the Medical Sciences*, October, 1885, Dr. Landon Carter Gray says: In five cases of progressive muscular atrophy I have given strychnia in doses up to gr. $\frac{1}{25}$. In all of them it acted as a remarkable stimulant, inducing such a sense of well being that most of them have felt the need of it when it was discontinued, so that several take it continuously. In one very marked and typical case $\frac{1}{30}$ to $\frac{1}{25}$ of a grain has been taken daily three times for nearly two years. In none, however, was there any real improvement. Dr. S. Weir Mitchell, in his work on the treatment of neurasthenia by rest and forced feeding, recommends strychnia in doses of gr. $\frac{1}{30}$ at the time when patients are to be taken out of bed. I have pursued this plan in a number of such cases, and have satisfied myself that it is invaluable. But, singular to say, three cases of neurasthenia, which were treated in the general way, bore strychnia in gr. $\frac{1}{10}$ doses badly, severe toxic symptoms being induced in two. I have never felt it safe to exceed gr. $\frac{1}{20}$. Indeed, even when giving $\frac{1}{50}$ or $\frac{1}{40}$ of grain, I have always been on my guard, because I have on several occasions found the action of the medicine to be cumulative. It was notably so in the case of transverse myelitis with contracture. Nor have I ever been able to dispossess myself of scepticism as to the benefits to be obtained from a toxic dose, which may possibly vary in amount with each individual and each disease, and I have therefore refrained from increasing the dose beyond the first toxic symptoms.

Extensor Tendons of the Fingers.—Besides some interesting researches on the synovial sheaths under the posterior annular ligament, Dr. Wenzel Gruber has recently described in Virchow's *Archiv* a tensor ligamenti carpi dorsalis, not hitherto observed. It existed in both fore arms of a woman. It was short and fusiform and arose from the ridge of the ulna between the extensor ossis metacarpi and the extensor secundi internodii pollicis, lying between them, above and between the former muscle and the short extensor of the thumb lower down. It ended in a short ribbon-like tendon, which was mostly lost in the posterior annular ligament, but some of the fibres were attached to the bony ridges which bordered the broad grove for the radial extensors. Dr. Gruber has also described a case where a peculiar arrangement of the extensors of the fingers existed. He had previously noted that an extensor digiti quinti et quarti proprius existed in about 10 per cent. of several hundred subjects under his inspection, though often unilateral. In this case, both the special muscle existed and also a distinct division of the muscular part of the common extensor, supplying a tendinous slip to the ring finger in the left hand and another to the little finger. As those fingers also received a tendon each from the main part of the common extensor, they were unusually well supplied. The supernumerary extensor, springing from the common extensor, ran in a special sheath under the posterior annular ligament. In the language of the English dissector, there were in this case two tendons supplied to the ring and little fingers from the common extensor, whilst the extensor minimi digiti divided into two tendons, one going to the ring, the other to the little finger. A tendinous band ran from the first metacarpal bone to the back of the capsule of the metacarpo phalangeal joint of the index finger.—*British Medical Journal*, Nov. 25, 1885.

THE DURATION OF THE ACTION OF MEDICINES

"Does our present knowledge support the view that medicines act during definite periods, that is, can we rely on a given dose of a drug influencing the organ in which it acts for the same space of time in different individuals, or on the same individual at different times?" Such is the question asked by DR D J LEECH in a most interesting introduction to a discussion before the recent annual meeting of the British Medical Association The question is not only highly interesting in itself, but far-reaching, and one to which but too little attention has been given It directly involves another question, Is not the frequency with which doses of medicine are given, in a great many cases, simply a matter of routine? "At the present time one of the leading objects of the therapeutist is to alter the functions of certain tissues or organs, temporarily or permanently Sometimes we aim at restoring the normal functions of parts, sometimes we desire to modify functions for a time, and thus neutralize evils arising from a disordered condition of other parts on which we cannot act But whether our purpose be to restore or modify, we know it can rarely be attained except by acting on the tissues or organs we wish to influence, with a certain degree of continuity, and we should endeavor, therefore, to repeat our medicines in such doses, and at such intervals, that the continuity of action we desire may be attained"

Our knowledge of the time during which a drug will act on an organ, though it should be the basis of our intervals for administration, is unfortunately but too limited, and as regards the causes which lead to variations in the duration we may be said to know almost nothing There are so many factors in the case, and so many causes of error, that the difficulties in the way of exact determination are very great The time at which absorption begins must vary in given cases, and when medicines are given *per os* no action can take place until absorption begins Some preparations are less soluble in the stomach than others, even of the same drug Or a very slight alteration in the condition of the stomach may cause delay in this respect When the action of a drug is unduly delayed we naturally attribute it to delayed absorption Again, the action may be delayed by insusceptibility to the drug in a given case, or diminished susceptibility of the organ in the same case at different times Still further, "when drugs act in a similar manner on the same tissues, the relative periods of their activity may vary distinctly" This is shown by comparing the duration of the action of ether and alcohol, the two drugs affecting the same tissues and functions, and the symptoms of intoxication produced by each being the same

And here it may be pointed out that in spite of our want of knowledge on this subject, we have learned by experience that there is a relative uniformity in the period of activity of many drugs, while ammonia acts quickly on the heart, its effects are evanescent, but while the tonic effects of digitalis appear but slowly, they last for a long time "Of our diuretics, purgatives, and emetics, some act for a shorter, some for longer, period The diuretic effects of caffein, for example, soon cease when we stop the administration of this drug, whilst the increased flow of urine which is produced by digitalis usually goes on for a long time, sometimes for several days, after the medicine has been discontinued The difference in the period during which these two drugs act, may of course depend on the fact that they exert their influence on different tissues Caffein, it has been suggested, stimulates the tubular epithelium, whilst digitalis causes diuresis through its effects on the vascular system But the relative difference in the duration of action must certainly be dependent on the fact that each influences the tissues it affects for a more or less definite period of time" In this connection may be mentioned the resemblance between the phenomena produced by amyl nitrite and the nitrites and nitro glycerine, as pointed out by Brunton, Cash, Murrell, Hay and others Though this resemblance is very strong, the duration of the effects of amyl nitrite is very much shorter than in case of the other drugs, and Hay has shown that the influence of sodium nitrite on arterial tension is much more persistent than that of nitro glycerine

Dr Leech's experiments on the duration of the action of drugs were limited to the effects of a very few drugs on arterial tension, the drugs being amyl nitrite, ethyl nitrite, nitro glycerine, sodium nitrite, potassium nitrite, and helleborein The phenomena produced by the nitrites and nitro-glycerine vary considerably in different individuals While some persons can take five drops of a 1 per cent solution of nitro glycerine, or even more, without unpleasant effects, others are disagreeably affected by one drop The persons selected for experimentation were of different susceptibility, and normal tracings were taken previous to the administration of the drugs The subjects were all free from cardiac diseases, and the observations were made, so far as possible, under similar conditions as to time of day, food, etc With amyl nitrite the influence on the pulse commences immediately after the inhalation, and the tension is reduced to its lowest point in from thirty to sixty seconds, "the blood-pressure then rises again, and usually attains its ordinary height in a minute and a half," as Murrell states In some cases, however, from two to four minutes elapse before the pressure rises In quite a number of cases, also, the tension may again fall after the first apparent recovery, and the return to the normal does not take place for eight or ten minutes In still other cases there may be a slight fall after the second return to the normal, and the effects will continue for twenty minutes or half an hour Alternations of this kind, says Dr Leech, occur during the action of all the nitrites, and he refers to them as oscillations In one case the effect of amyl nitrite was traceable for more than an hour While, therefore, the effects of this drug vary considerably, "its very marked tension-reducing influence never lasts more than one and a half to two minutes, but a slight depression of blood pressure is commonly present for a longer period, and not only does the duration of the influence of the amyl-nitrate differ in different people, but it is also variable in the same individual at different times"

With nitrite of ethyl the tension is depressed for a much longer time than with nitrite of amyl, and in quite a different manner "A dose of 25 minims of a 25 per cent solution, in alcohol, causes, in those susceptible to the influence of the nitrites, a slight fall in tension within a few minutes, but, as a rule, the greatest effect is not noticed until from six to fifteen minutes nave elapsed For twenty or thirty minutes longer, the tension continues low Then a return towards the normal takes place, usually with oscillations I have traced the effect of this nitrite for two hours Where the dose is small, or in those not susceptible to the action of the nitrites, hardly any fall is seen during the first half hour, and the normal tension is regained in about an hour and a half" From some experiments made with spirit of nitrous ether, Dr Leech believes that seven or eight minims of pure ethyl nitrite will "usually keep the tension depressed for at least forty-five minutes, in some people for rather more than an hour," and he thinks that the effect on the circulation often persists during the whole of the second hour But while the depression of tension is more prolonged than in the case of amyl nitrite, it is not so great Nitro glycerine not only acts more powerfully and quickly than ethyl nitrite, but its effects are more prolonged "A single drop of a 1 per cent solution causes a fall in the pulse tension in one and a half to two minutes, and in three or four minutes the fall is well-marked" The pressure continues low for about ten minutes, or a little longer, then gradually rises to almost normal in about half an hour But on account of the oscillations the normal is not perfectly reached until the lapse of an hour or an hour and a half As already stated, however, this drug affects some persons more powerfully and for a longer time than others With sodium and potassium nitrite—the alkaline nitrites—while the effect is not so quick as with nitro glycerine, the duration of the effect seems to be more prolonged Dr Leech estimates that "whilst the average duration of five grains of an alkaline nitrite in ordinary individuals is about five and a half hours, the effect of three grains does not last so long by half an hour"

While it is seen by the preceding sketch of Dr Leech's paper, which is to be found in the *British Medical Journal*, of Nov 28, that but a very limited number of drugs were experimented upon, and the the experiments limited to their effects on arterial tension, we must regard the contribution as one of great value, and as in part opening the way to very important work It would seem, too, that the question of the duration of the action of drugs must be primarily included under the department of pharmacology, and thence be extended to the duration of the action of medicines in disease And certainly, while the field is practically boundless, there are mines of wealth at every turn

AMERICAN MEDICAL ASSOCIATION, ITS NEXT ANNUAL MEETING

As the next Annual Meeting of this important National organization will commence on the morning of the first Tuesday in May, 1886, in St Louis, Missouri, only four months remain for those who are contemplating the presentation of papers, reports, or any matter of interest, to complete their preparation. To ensure a profitable meeting, and especially one of high scientific interest, it is necessary that preparations should be commenced early and a systematic programme of work arranged for each Section. The ordinary routine of miscellaneous business, with the addresses of the Chairmen of Sections, usually fully occupy the general morning sessions during the four days occupied by the Annual Meeting. Indeed, unless these officers, in the preparation of their annual addresses, adhere more closely than usual to the requirements of the by-laws, it will be impossible to crowd them all into the time allotted to the general sessions, and, as on former occasions, some will be read only by their titles and referred, a practice which should not be encouraged.

The by-laws require from the Chairman of each Section an Address on the discoveries and improvements made in the branches included in his Section, during the preceding year, and that not more than *forty minutes* shall be consumed in its delivery. Two objections have been made by former Chairmen of Sections against a literal compliance with the requirements of the rule. The first is that the actual discoveries and improvements made in most of the branches of medical science, in any one year, are not sufficient to constitute the subject of an address; and the second, that all such discoveries are at once published in the medical periodicals, and consequently their re-statement in a public address would be only repeating what is already familiar to the profession. A closer examination will show that neither of these objections are well founded.

A careful student of current medical literature cannot fail to discover, during every year, items of progress, proposed changes, and suggestions supposed by their authors to be new, in some parts of the field covered by any one of the Sections, sufficient to constitute the basis of a most interesting discourse of thirty or forty minutes. Again, while it may be true that every new idea or supposed discovery, and every suggested improvement, finds its way to the profession through the columns of the medical periodicals, it is not true that every member of the profession takes all these periodicals or finds time in the midst of the practical duties of the profession to examine critically those he does take. Consequently some items of importance escape his attention, and some that he does observe are of such a nature that he has not time to examine the evidences on which their claims to importance rest. If the Chairman of a Section should simply cull from the pages of the medical periodicals a list of the alleged discoveries and items of advancement, we admit that his discourse would possess comparatively little interest. But it should be his object not only to present such a list, but to critically examine and point out the evidences on which each item rests for its claims to our confidence. He should show what items are really new and what are merely old ideas or modes of practice, clothed in the novel phraseology of a new theory. He should also critically examine the methods of investigation by which alleged facts or conclusions have been reached, showing defects where such exist, and suggesting remedies for them. A series of such addresses, each kept rigidly within the limits of time prescribed by the by-law, delivered by the Chairmen of the Sections before the members of all the Sections in the general sessions, would afford not only a most interesting and profitable annual review of the various departments of medicine, but their subsequent publication in THE ASSOCIATION JOURNAL would bring the same to the attention of the whole membership and exert an important influence in promoting better methods of investigation and avoiding conclusions based on only a partial observation of the facts.

Perhaps the most important part of the work of preparation for the next Annual Meeting, however, is that relating to the programme for each of the Sections. If this is left entirely to the voluntary offering of papers, experience has shown that while some Sections will have more than there will be time to hear, others will be comparatively unoccupied. To avoid this, the Chairman and Secretary of each Section should invite a sufficient number of thoroughly competent parties to prepare contributions on important topics, to secure at least one or two leading papers for each of the three sessions of the Section, and one or two equally well-qualified members to open the discussion of each paper. Having secured this much, they can safely trust to voluntary contributions for filling up all the rest of the time profitably. If this part of the work has not yet been attended to, the officers of the Section should lose no more time before engaging earnestly in the work before them, remembering that the best answer to all those who have been indulging in depreciative remarks in regard to the Association, is a meeting in St. Louis characterized by earnest, thorough and important scientific work in every Section. To facilitate the correspondence, we have placed under the head of "Association Items," the names and address of the general officers of the Association and of the several Sections.

SOCIETY PROCEEDINGS

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirteenth Annual Meeting, held at Washington, D C, December 8, 9 and 10, 1885

(Continued from page 714, Vol V)

Wednesday, December 9—Second Day

Afternoon Session

Hon Erastus Brooks in the Chair

Dr Granville P Conn, of New Hampshire, read the

REPORT OF THE COMMITTEE ON STATE BOARDS OF HEALTH

The report concludes as follows

First That it is the judgment of the Committee that in carrying out the object of their creation it is necessary to have a conference of delegates from State Boards of Health at least once a year for the purpose of consultation and to promote unity of action on matters essential to public health, the prevention of epidemics and the most efficient means of instructing the people in sanitation

Second The Committee would suggest that the most suitable occasion for holding this conference would be during the annual meeting of the American Public Health Association, and that our President and Secretary arrange the time of the meeting in connection with the Executive Committee of the American Public Health Association so as best to promote the interests of the Association and the conference

Third Any conclusions of this conference that are of interest to the public shall be reported by the Secretary to the American Public Health Association, through the standing Committee on State Boards of Health

REPORTS OF STATE BOARDS OF HEALTH

Dr J N McCormack, Secretary of the State Board of Health of Kentucky, submitted a brief report of the operations of that Board for the past year, and indicated an increased interest in health on the part of both the profession and people of that State His Board attached the utmost importance to the recently enacted law providing for instruction in regard to the plain laws of health in all public schools, but has not been successful in finding any text-book suited to this purpose—most of those now in existence being only treatises on anatomy and physiology, with deficient, crude or misleading instruction on the important subject of the prevention of disease He referred to the recently published account of the investigation of the fever endemic in Louisville, and stated that no practical result had so far followed except the worthless one to substitute tube wells seventy-five feet deep for those now in use

In the discussion that ensued, the various States were called Dr Kennedy, of Iowa, said that the law of his State gave the Board almost absolute power to vaccinate everybody under 21 years of age

Dr Gerrisch, of Portland, Maine, reported how the Board of Health of his State had been organized last year, but three votes out of 181 in the Legislature being opposed to it The sum of $3,000 was appropriated for it the first year He thinks $5,000 will hereafter be appropriated annually, as well as $5,000 additional to be used as an epidemic fund But two cases of small pox have occurred in his State since the outbreak of the disease in Montreal

Dr Henry B Baker, of Michigan, added that the Board of his State and the people have been unusually active during the past year in taking all the necessary precautionary measures to prevent small-pox and other contagious diseases

Dr Cox, of Missouri, said the Board of his State had all things well under headway to avert any epidemic of small pox or any other epidemic disease The water supply was well arranged, and wholesome water was almost universally used throughout Missouri

Dr G P Conn supplemented his paper by the remark that the work in his State Board had been similar to that of other States The people there demand protection through the State Board of Health But one family, coming direct from Montreal, has had small pox in his State for many months, and that occurred in Manchester, although 1,000 people had come to Manchester from an infected district in and about Montreal

Dr Ezra M Hunt, of New Jersey, said his Board had been well sustained by the people The report on tenement house inspection and inspection of schools has been put in book form and was favorably received

Hon Erastus Brooks, of New York, said that their Board was a very efficient and thorough organization In 1,000 towns, 240 villages and twenty four cities there are local boards of health In a number of the cities they are distinct and independent organizations, and independent of the general law They are trusted to establish their own local board, and at least one competent person is selected to take care of the interests of the locality The appropriation for the State Board of Health was $20,000 for the past year The Secretary receives $3,500 a year, and he is the Board's executive officer The city of Brooklyn expends about 75,000 a year for sanitary purposes

Dr Thos F Wood, of North Carolina, stated that the Board of Health of his State had been reorganized since the last meeting of the Association, the legislature of January, 1884, appropriated $2,000 for the Board, and $2,500 as contingent fund to experiment on drinking water, etc Of ninety four counties in North Carolina, fifty counties have organized local boards, and a plan for registering vital statistics

Dr R Harvey Reed, of Ohio, thinks that a State Board of Health will ultimately be established in Ohio In his State there have been divisions upon this subject, even in the State Medical Society Some bills presented in the legislature have been too short and others too long A committee is now at work from that Society preparing a bill to present to the Legislature Another thing to contend with is that many quacks are in that State They work against the organization of a State Board These quacks are very numerous, being driven there from adjacent and other States of the Union

Dr Ashman, of Cleveland, Ohio, said there were many local boards of health organized throughout Ohio, $25,000 to $28,000 were expended yearly at Cleveland by the local board He thinks the prospect is not very good at present for the organization of a State Board

Dr Fisher, of Rhode Island, said that in his State, advancement is being made in public sentiment and in the practical performance of measures taken for the care of the public health, although personal liberty is what the people of his State dote upon, taking the view that a man should not be deprived of his liberty, and should live in as much filth as he likes Vaccination has been thorough in at least two thirds of the towns throughout his State since the epidemic of small pox has broken out in Montreal Rhode Island requires that pupils before entering school must be vaccinated, hence the State is well protected against small pox

Dr G B Thornton, of Memphis, said the State Board of Tennessee had been very materially strengthened at the last legislature, by two acts, by the first of which $10,000 a year and $5,000 are to be used exclusively for quarantine purposes The second provides for the creation of county health officers Such an officer must be a physician, and he reports to the Secretary of the State Board any case of cholera or any other infectious or contagious disease

Dr Swearingen, of Texas, said that in Mexico there were ten cases of small-pox to one case in Canada, yet but few cases ever occur in Texas, and no epidemic of any magnitude has ever broken out in Texas This is on account of the inspection service at El Paso

Dr J G Cabell, of Richmond, Virginia, stated that about fourteen years ago the Virginia State Board of Health was organized upon the basis that it should be at no expense to the State The Board consists of seven members No child in Richmond is allowed to attend school unless it has been successfully vaccinated

Dr James E Reeves, of Wheeling, briefly stated that West Virginia owed this Association much for its State Board of Health In 1881 there was not a health board worth the name in the entire State, while now, a board is organized in all the counties and municipalities throughout the State

Dr J T Reeve, of Appleton, Wis , said that some progress has been made in his State during the past year, stimulated by the anticipated approach of cholera $30,000 was appropriated by the last legislature, and $15,000 for each of two years before it meets again, as a contingent fund for cholera or other epidemics, although the State has been free from epidemics of all kinds Small pox has visited the State but two or three times during the past year, but it was confined to a single case in each instance The two cases came direct from Montreal, and prompt measures stamped it out From the last two cases there arose, in all, eighteen cases, with a result of five deaths, which occurred in a town of 10,000 people

Dr I S Covernton, of Toronto, Canada, said that out of 660 local boards of health that had been established in Ontario, 520 had sanitary inspectors Disposal of sewage is being properly attended to throughout his Province $3,000 a month for the past four months has been expended to stamp out small pox in the Province

Dr Wm H Hingston, of Montreal, said that 250 boards have been organized during the past two months in the Province of Quebec

Evening Session

The President in the Chair

Dr Benjamin Lee, of Philadelphia, read a paper entitled

THE DEBIT AND CREDIT ACCOUNT OF THE PLYMOUTH EPIDEMIC,

on the Credit side being placed the "State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania," and the following on the Debit side Cost of illness of 1153 cases, $59,100 17, expenses of hospital, $8,000, loss of earnings during sickness, $30,020 08, capital represented by loss of income, of 114 persons who died, at three per cent *per annum*, $613,984, total, $711,104 25

The total number of sick was 1153, the population being estimated at about 8,000 Of the number attacked with the disease 114 died The proportion of deaths in the hospital was about three per cent , which is unsurpassed by the record of any other hospital in the world The expenses incurred by the epidemic are estimated at $67,100 17, of which amount $8,000 was consumed in running the hospital Of those who were ill with the disease and recovered the loss of earnings during illness was found to be $30,020 08 Thus the total cost of the epidemic is reckoned at $97,120 28 By the 114 deaths a monthly earning of $1,534 96 ceased, showing a loss of $18,419 52 per year in incomes The State Legislature contributed $5,000 for the maintenance of the hospital The State of Pennsylvania therefore disbursed directly from its treasury for the relief of the sufferers from this single outbreak of preventable disease, precisely the same amount of money that the Legislature now allows for the expenses of the Board which is to have the supervision of the health interests of her people, for an entire year And this brings us to the credit side of the Plymouth epidemic But for that sad calamity the efforts of physicians and philanthropists to obtain the establishment of this essential department of every civilized State would have been as unavailing as at any time during the past ten years This practical demonstration was an argument which the dullest could appreciate, the most bigoted could not withstand And so, out of the agonies of Plymouth the State Board of Health of Pennsylvania was born

Dr E M Hartwell, of the Johns Hopkins University, read a paper on

THE GERMAN SYSTEM OF PHYSICAL EDUCATION

He prefaced his paper by several well chosen remarks upon sports, gymnastics, physical training, etc , in Germany Not until 1860 was physical training made obligatory in the public schools in Germany, and three or four years ago in Prussia it was also made obligatory for girls It is obligatory for the boys in the Prussian schools to train two hours every day They begin at the age of 6 and continue it until they are 19 or 20 years of age The system is better organized in cities than in the country In Berlin in 1881 there were 15,998 pupils in the high schools, of which, in round numbers, 11,000 were boys and 4,000 were girls Having described the origin of "turning" or gymnastics among the Prussians and the consequent Turnvereins, so numerous throughout Germany, he turned to the subject in its present national aspect He said that in the German schools, both for boys and girls, gymnastics are compulsory, and in 1879, out of all the scholars in the classical and high schools only ten per cent were excused from the two hours' weekly class of physical gymnastics, and those only on the certificate of a physician stating that it would be injurious for them to attend the class There are in Berlin ninety-eight gymnasiums, and in 1880 and 1881, of the $1,760,000 appropriated by the city for educational use, one thirtieth of that amount was expended for the teaching of gymnastics

There are a thousand teachers in Berlin who are capable of giving gymnastic training They, for the most part, do so in connection with their other classes, but they must first go through a regular normal school of gymnastics In 1885 there was appropriated for the Royal Normal School for Gymnastic Teachers, established at Berlin in 1851, something over $21,000, and here teachers from all over the German Empire come to learn, so that they may go back home and teach their pupils Details of officers from the army become pupils so that they may teach the soldiers, and the effect of this training is seen in the superiority of the German soldiers They can get over a picket fence fifteen feet high without ladders and without catching any of their clothing or accoutrements The Germans introduced gymnastic exercise into America, and we could not do better than to embrace their system, adapting it, of course, to our institutions, thus enabling our youth to bear the brute strain of study

DR O W WIGHT, Health Officer of Detroit, read a paper entitled

EXPERIMENTS IN DISINFECTING SEWERS

Detroit has no regular sewer system The city is traversed by more than a score of great conduits, from four to eight feet in diameter, from two to seven miles in length Most of them empty into the river submerged, consequently the dead water sets back in them from 1,000 to 5,000 feet At their lower ends they are ordinarily choked with sediment, which is sometimes washed partly out in great storms The submerged mouths are pretty effectually trapped, making these huge conduits receptacles for vast volumes of sewer-gas A rapid increase of water in the big sewers, during a summer shower, has sometimes caused such internal pressure of the confined air as to throw off covers from manholes in the streets The effect on traps in the drains of houses can be easily imagined The lateral sewers are constructed of common porous brick, thrown together by cheap workmen, and are all twenty inches in diameter, whether designed to drain five acres or fifty acres Sewer empties into sewer, frequently at right angles, sometimes at the top, sometimes at the bottom Now and then a large sewer is connected with a smaller one Here and there depressions allow the sewage to become ponded and undergo putrefactive decomposition In places, the constructors have evidently expected water to run up hill, in obedience to the wishes of a favored contractor Recently, more than twenty large saw logs were extracted from a single sewer, fifty or sixty rods back from the river More than ten thousand vaults are connected with the sewers, for the most part by means of eight inch clay or cement pipe, laid without tight joints or traps No wonder Detroit has annually more than a thousand cases of diphtheria Doctors there used to tell the people that they had the best sewer system in the world and that their city was the healthiest in the United States

Notwithstanding the fact that two medical men descended into one of the great sewers, remained there, to use their own language, "twenty four consecutive minutes," and not only came out alive, but announced to an expectant public that the air therein was ' chemically pure," I determined to disinfect the 200 miles of sewers and see what would come of it The work of disinfection was begun with copperas There are in the streets and alleys of Detroit about 5,000 receiving basins communicating with the sewers Into each of these were thrown a dozen pounds of copperas To each school house, police station, fire engine house, and to every other public building, a barrel of copperas was sent, at the city's expense We used 75,000 pounds of copperas, purchased by the carload, at $13 a ton At the same time I made an arrangement whereby citizens could purchase, of a wholesale dealer, copperas for one cent a pound As nearly as I could calculate, the citizens purchased and used about 200,000 pounds during the season The direct and indirect effect on the sewers, from the use of nearly 140 tons of copperas, was to disinfect the sewage for several successive weeks The citizens found so much comfort from the disinfection of their foul smelling drains that, with many of them, the use of copperas has become habitual It is very true that copperas, or any other disinfectant, is not a perfect substitute for good plumbing and proper drainage, but it does something toward remedying a prevalent sanitary evil

To destroy the poison in the confined foul air of sewers, also to kill the fungoid growths on their inner walls, a gaseous disinfectant is necessary I therefore determined to fumigate the sewers with burning sulphur Three tons of roll brimstone were purchased at a total expense of $150 Fifty galvanized iron pails, called steamboat pails, were purchased, at seventy five cents each A sufficient quantity of light chain, and five dozen spikes, with hooks in the place of heads, were also purchased Holes three quarters of an inch in diameter were punched in the iron pails about two thirds of the way up from the bottom, two inches apart all the way around. Procuring from the Board of Public Works the services of two men experienced as to the location and construction of the sewers, loading up a wagon with a barrel of sulphur, a nest of pails, perforated as aforesaid, a quantity of chain, a pair of nippers, a hammer, pick, shovel, crowbar, shavings, bundles of short wood faggots, and a barrel of charcoal, I started out amid the jeers of a disbelieving crowd of city officials.

With shovel, pick and crowbar, the cover of a manhole was lifted when we reached the place of our destination. A spike, with a hook on the end of it, was driven into the wall of the brick well, a foot or two below the top, the chain was fastened to the bail of an iron pail and the same let down into the sewer, so as to swing just clear of the sewage running in the bottom. The chain was then hooked on the spike already driven. The nippers served to cut off the chain above the hook. The pail was then drawn up, leaving the adjusted chain attached to its fastening. Into the pail were put, first, a handful of lighted shavings, then on the burning shavings some faggots of wood, and lastly, on the igniting wood a small scoopful of charcoal. Over the pail was placed a sheet iron cover, in the centre of which was inserted a single length of conical stovepipe, eight inches in diameter at the bottom and four at the top. The air rushed through the holes punched in the pail with a good draught, hastening combustion and thereby saving time. As soon as the charcoal was thoroughly aglow, the cover was removed, a dozen pounds of brimstone were thrown on the hot fire, and the pail, by means of its already adjusted and fastened chain, was quickly lowered into the sewer. It only remained to replace the cover of the manhole. We drove on to the next manhole, four or five hundred feet away. Removal of the cover revealed not only smoke, but also a strong odor of brimstone. Sulphurous acid gas traveled in the sewer as fast as we did on the road.

The work went steadily on, day after day, till a pail of burning brimstone had been suspended down each one of the 500 manholes in the city. The pails were taken up the next day following suspension, and not unfrequently, remnants of sulphur were found burning after twenty four hours. Not a single pail missed fire. If ordinary means of igniting the brimstone had been used, there would have been many failures and much loss of time. The odor of burning brimstone demonstrated to many a citizen that his drains and waste pipes were not securely trapped against sewer gas. When the work was completed, the people were so convinced of its efficacy that the Board of Education resolved to have all the school buildings fumigated, in each of which, according to the size, were burned from thirty to eighty pounds of brimstone. There followed the copious use of copperas and sulphur a great abatement of diphtheria and an almost total cessation of scarlet fever.

Of course, a single experiment does not warrant us in predicating a relation of cause and effect. The whole expense for a single disinfection of the sewers with copperas and burning brimstone was less than $1,300. With the money left out of the appropriation, we have this year repeated the experiment. Again we have treated the sewers of the city to 60,000 pounds of copperas and three tons of burning sulphur. The Board of Education has adopted the plan of fumigating the school buildings twice a year. The second experiment was followed, for a time, by an almost complete cessation of diphtheria. Again I say that disinfection, however thorough, is only a temporary relief from a dangerous evil, and cannot be relied on as a substitute for an unsound sewer system and radically defective house drainage. The expense is not great, and it may be used as a more or less valuable instrumentality in a season of epidemic peril.

Dr. Rohe hoped that Dr. Wight would disinfect and fumigate the sewers of Detroit in winter and let the Association hear the result of his experiments.

Mr. C. C. Dewstoe, of Cleveland, Ohio, said that plumbing and sewerage ought to come under the direction of Boards of Health.

THURSDAY, DECEMBER 10—THIRD DAY.

MORNING SESSION.

HON. ERASTUS BROOKS, FIRST VICE-PRESIDENT, PRESIDING.

The following were

ELECTED MEMBERS:

Drs. Andrew W. Imrie, Detroit, John W. Jones, Tarborough, N. C., Frank L. Simm, Memphis, J. Howard Taylor, Philadelphia, Charles Farquhar, Olney, Md., Carl H. Horsch, Dwight A. Richardson, Osceola, Ark., Thos. Taylor, Jas. T. Young, Z. T. Somers, P. Morgan, Jr., Washington, D. C., Mr. Ed. J. Hannan, Washington, D. C.

The following resolution, offered by Mr. Henry Lomb at Wednesday's forenoon session, was adopted by the Executive Committee:

COMMISSION ON WORKSHOPS.

Resolved, That the American Public Health Association respectfully recommend to the Commissioner of Statistics and Labor the appointment of one or more commissions of experts whose duty it shall be to visit the principal factories and workshops in this country to examine them carefully with reference to the provisions made in them to ensure the safety and health of the employes, and to report on the same, with recommendations.

Dr. John H. Rauch, Secretary of the Illinois State Board of Health, then read a paper on

MARITIME QUARANTINE FROM THE ST. LAWRENCE TO THE RIO GRANDE.

After taking the necessary action to secure the best attainable sanitary condition of the territory under its immediate jurisdiction—as one of the most important preparations against an invasion and spread of Asiatic cholera—the Illinois State Board of Health, at its meeting in July, 1885, authorized me, as its Secretary and Executive Officer, to make an inspection of the various quarantine establishments along the Atlantic and Gulf coasts. The geographical position of Illinois, its commercial relations, and the extent and character of its means of communication, make the administration of maritime quarantine with reference to the exclusion of exotic contagious and infectious diseases a matter of sufficient importance to induce the Board to secure all accessible information on this subject, the better to enable it to discharge its duty with reference to the protection of the lives and health of the citizens of the State

The absence of an adequate National Health authority and legislation, and the fact that in such absence the maritime quarantines are controlled and administered by State authorities, resulting in diverse and sometimes conflicting regulations and requirements, and of necessity, in a tendency to limit precautions to their own individual interests, commercial as well as sanitary, throw upon interior States the responsibility of fully informing themselves of the strength or weakness of these outposts in order to know where to anticipate danger and how to make their own preparations to meet it It is this information I have endeavored to secure in my inspection, and which is here presented It is hardly necessary before this assemblage to say that we are by no means yet free from danger of an invasion of cholera simply because there is now a cessation of alarming reports from Europe It must not be forgotten that the duration of a cholera invasion of Europe is not limited to two or three years From the date of its first appearance in 1829–30, in Russia, to its final extinguishment in Italy, Austria and Germany, a period of seven years elapsed, during which, at one time or another, every one of the Continental countries was invaded, some of them more than once Similarly in 1847 it again entered Russia at ten points, and before its final disappearance in the Levant in the winter of 1855–56 it traversed every part of the the Continent and invaded Great Britain In its last pandemic spread it appeared first at Malta in 1865, continued to ravage various parts of Europe until 1869, when there was a complete remission, only to break out again in 1871, and finally disappear in 1873 With immigrants from every portion of Europe continuously arriving upon our shores, we cannot be freed from this menace until every trace of the contagion in that country has vanished

When this inspection was ordered it was believed that it might be productive of good in stimulating improvements, and in presenting more clearly the interest of distant communities in the administration of what is apt to be considered a purely local measure This belief has been fully realized, and the results obtained have been well worth the labor and expense involved

From the date of the earliest establishment of quarantine in this country down to the present time, its efficiency and the public interest in it have been fitful and spasmodic, depending on some pressing emergency Small pox from the slave trade, yellow fever from West Indian commerce, and typhus and small pox by immigrants, led to the first quarantines, dating back to the close of the seventeenth century From 1791 for several years, yellow fever furnished the impetus, then in 1832 the cholera was added, and from that time up to the fever summer of 1878 there was no general interest in the subject, although quarantine conventions were held and the question was discussed by physicians and sanitarians, the most notable effort in this line being that inaugurated by Dr Wilson Jewell, of Philadelphia, who, in 1856, sought the establishment of "a uniform code of regulations, operating alike in all seaports and offering the least hindrance to an active commerce and with a humane regard for the health of the passengers and crews and the comfort of the sick on board of all vessels detained at quarantine stations" But notwithstanding the organization, in 1857, of a "Quarantine and Sanitary Convention" for this purpose, and which held annual sessions in 1858, 1859 and 1860, the control of quarantine has always remained under the jurisdiction of State and local authorities except during the brief period in which the National Board of Health exercised limited quarantine powers

It is not proposed to discuss the necessity for National action on this subject The National Conference of State Boards of Health and the American Public Health Association are both on record as to the importance and necessity of such action But mention may here be made to the existing confusion, not alone in this country, but abroad, as to the present status of National quarantine legislation Such sanitary measures as are now enforced by the Government are based upon authority derived from the Act of April 29th, 1878, to prevent the introduction of infectious or contagious diseases into the United States But the late Secretary of State, Mr Frelinghuysen, and the late Secretary of the Treasury, Mr Folger, both decided that the Act in question, having been repealed by the Act of June 2d, 1879, could not be revived by the expiration of this latter Act The point would have less practical importance if the authority which assumes to act under it can and will furnish the country the necessary protection in the present emergency As practical sanitary executives we are less concerned just now as to who exercises the authority and by what right, than in the questions Is the authority wisely exercised? Is it sufficient? May we rely upon it implicitly? If not, to what extent? And how can we remedy its deficiencies? It is by no means meant by this that it would not be better that there should be a properly organized National Health Department, acting under clear and undisputed legal authority, and supplied with funds adequate to its legitimate necessities That the present status of National sanitary legislation and of the National sanitary executive is defective and unsatisfactory, is patent to every one

The history of the recent attempts to control the disinfection of rags, the complication at the port of New York concerning consular bills of health, the strictures upon the inspection service maintained along the coast, the friction between the Canadian health authorities and our own in the matter of inspections on the Canadian frontier, the complaints of various Boards of Health that they are directed to look to the associated press for information and warning concerning threatened danger from abroad to their ports and territory, and many other similar matters, point to the necessity of a well considered and radical revision of existing sanitary legislation No sanitarian will, I presume, question the danger of communicating pestilential diseases by infected linen and rags At the Fifth International Congress of Hygiene, at the Hague, in 1884, Ruijsh cited a mass of proof which is conclusive as to the numerous outbreaks of plague, small pox, petechial typhus and Asiatic cholera caused by handling, sorting and carrying rags In the absence of any national authority cargoes of such rags refused entry at certain ports have been received at others

As to consular bills of health, want of direct and official information concerning the sanitary condition of foreign ports and other counts in the above summary, they are essential to the prevention of the introduction of foreign contagion

DR JOS HOLT, of New Orleans, read a paper on

THE SANITARY PROTECTION OF NEW ORLEANS

He spoke of the means which had not yet been taken by New Orleans for the sanitation of the city, but toward which he said the people were being educated by the Health Board and by the intelligent press Already a plan was being prepared for the systematic and thorough sewerage of the city Maritime sanitation had taken the place of quarantine along the coast The theory of bacillic origination for the essential cause of diphtheria, consumption, small pox and yellow fever has passed from the realm of uncertainty into a crystallized fact Even in our religion, incantations and long drawn prayers are no longer looked upon as disinfectants We have tried these and have invariably been swamped We are no longer fighting the devil and the devil's works, but a microscopic germ—a little leaven which, if not speedily eradicated, leaveneth the whole lump Yellow fever and cholera are due to living organisms, and it is to the destruction of these that our efforts are directed The surest prevention of a conflagration is to quench the first spark The surest prevention of an epidemic is to act on the first suspicion of the presence of epidemic disease We disinfect every ship coming from cholera or yellow fever regions, regardless of bills of health or the angry cry of trade mongers Should you ask why does not the commerce of New Orleans sweep the circuit of the world? why it has not grown as other large American cities? I would answer in one compound word—yellow fever

Dr Holt spoke at length upon the success of inoculation for yellow fever It has been proved that the germ can be inoculated in the body of the unacclimated person, and that a mild form of yellow fever will be produced thereby The persons who have been thus inoculated have been enabled to pass through most virulent epidemics unscathed In concluding his paper, Dr Holt said that the principal object of his visit to Washington was to present the following resolution to the Association to bring to the attention of Congress

COMMISSION ON YELLOW FEVER

WHEREAS, The question of immunity from yellow fever is so intimately associated with the social, industrial and commercial growth of Tennessee, the Southern Atlantic and the Gulf States of the Union, as to determine the destiny of Memphis, Charleston, Savannah, Pensacola, Mobile, New Orleans, and Galveston, and

WHEREAS, A large and accumulating mass of testimony that the power of protecting the unacclimated against yellow fever, has been discovered, and proven in the inoculation of the essential germ or cause of the disease by methods distinctly formulated and available, these aforesaid declarations and numerous instances cited in corroboration emanating from medical scientists in the biological departments in the highest institutions of learning in Mexico and Brazil, authorized by and bearing the endorsements of the respective Governments,

Resolved, That we, the representatives of the Boards of Health in the several States of this Union, and we, the officers and members of the American Public Health Association, regarding the question as preeminently a vital issue, as one in its assumptions true or false, and if true, of incalculable worth, surpassing the computation of many millions of dollars and to the saving of tens of thousands of lives of its own people, that we hereby petition and urge upon both branches of Congress now assembled, to appoint a commission for the purpose of making a complete investigation of and reporting after a thorough examination of the methods pursued, their effectiveness in protecting the unacclimated against yellow fever infection, together with all associated observations and experiments that may be ascertained

Resolved, That in the aforesaid petition the commission shall be stated to consist of three persons, one of whom shall be of known ability and special attainment in biological research, particularly in the department of microscopic investigation and culture of the essential germ or organisms causative of the infectious or contagious diseases The other two members of the commission shall be medical men of recognized ability based upon long and ample experience, competent to give expert consideration to all phases of the symptoms and course of yellow fever in any form wherein the phenomena of the disease may present itself, whether induced in the course of pestilential invasion or in purposely devised inoculation

Resolved, That this commission aforesaid shall proceed at the earliest practicable moment to Rio de Janeiro as the first field of its labors Having completed there its work, it shall proceed to Mexico, and if necessary in the accumulation of testimony, to Panama, Colon, and Havana

Resolved, That the sum of $30,000, or so much thereof as may be actually required to pay the necessary and unavoidable traveling and other expenses and the salaries of the members of the Commission

Resolved, That the sum of $5,000 shall be paid as a recompense to each member of the aforesaid Commission

DR S T ARMSTRONG, U S Marine Hospital Service, read a paper on

MARITIME SANITATION,

in which the subject was considered from the standpoint of the sailor, the passenger, the cargo, the vessel, and the port. Attention was directed to the necessity of legislation for preliminary examination of seamen, before shipment, of a required minimum cubic space in the sleeping quarters of the crew, of inspection of passenger and emigrant vessels regarding health of passengers, crew, etc., by medical officers of the Treasury Department instead of Collectors of Customs.

Disinfection of cargoes and vessels from infected ports, both by shipmasters and by inspecting officers at the port of arrival. The sanitary condition of the port was only alluded to, as the author considered this the special province of the Association, and if ports were in a good sanitary condition but little danger may be anticipated from imported disease.

DISINFECTION OF RAGS.

The Philadelphia Board of Health asked the Association to pass resolutions that rags should not be admitted to this country until disinfected.

At 1 o'clock P.M. the Association adjourned to call upon the President at the White House, according to special arrangement.

At a meeting of the Executive Committee immediately after the adjournment of the morning session at 1.30 o'clock, it was decided that the next annual meeting of the Association should be held at Toronto, Ont.

(*To be concluded.*)

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA.

Stated Meeting, December 9, 1885.

VICE-PRESIDENT W. H. TAYLOR, M.D., IN THE CHAIR.

DR. SWAN M. BURNETT presented a boy suffering from

TUBERCULAR DISEASE OF THE IRIS,

and gave a history of the case.

Harry Haskins, white, aged 13. Seen for the first time at the Central Dispensary, on May 22, 1885. At that time there was iritis of the R. E., accompanied by the usual symptoms of pain, injection, etc., and the use of atropine showed that adhesion had already taken place to the anterior capsule of the lens. There was also visible at the lower inner periphery of the anterior chamber a nodular tumor 2 mm. in length and 1 mm. in thickness and height. The tumor was of a light yellowish red. There was also a slight opacity of the cornea over this, and a leash of vessels running from the conjunctiva and passing over the surface of the cornea beyond the inner edge of the growth. There was simple perception of light in this eye. The left eye was at that time normal. There were hard, nodular, clearly circumscribed swellings at the upper outer angles of both orbits—apparently enlargements of the lachrymal glands.

In July, a small tumor exactly similar to the one in the R. E. made its appearance at the lower periphery of the L. E., and in the course of a week there was an eritis in this eye also. The active process in the R. E. had subsided, but the tumor remained unchanged or perhaps increased somewhat. The tumor in the L. gradually increased and in the course of a month or six weeks attained nearly the size it now is. The iritis subsided in the course of two or three weeks, but there was a slight renewal of inflammation in the R. E. a month ago, which subsided in a week. On September 29, when he presented himself, there was noted a small yellowish nodule at the outer lower papillary edge of the iris, and a month later a similar nodule at the upper edge of the papillary margin.

Soon after he was first seen, there was noted an enlargement of a post-auricular gland, and gradually since then other post auricular and sub maxillary glands on both sides have become implicated.

On inquiry, I learned that there is tuberculosis in the family. Under the idea of syphilis being at the bottom of the pathological state—though a careful examination failed to reveal any evidence of either the inherited or acquired form—he was placed on mercury and iodide of potash in small doses. The use of these remedies for several months, however, has failed to make any impression on the disease. I have seen one case of tubercular tumor of the choroid exhibited as a living specimen to this society three years ago, and there are certain points of resemblance in history and appearance in the two which make me almost certain that this case is one of tubercular deposit. The question is, if the eye had been removed when first seen, would self infection have been forestalled. I fear that I shall have the opportunity of presenting, at some time in the near future, the morbid specimen in this case.

DR. C. E. HAGNER said he had examined the boy's lungs and found the right one healthy. There was a broncho vesicular murmur at the top of the left lung together with some slight dulness of the same organ. He did not know whether enucleation would prevent further infection or not. He thought it would be well to put the patient under constitutional treatment for syphilis, as there was a possibility that the boy might be suffering from that disease. At any rate, mercury and potash in tonic doses could not do him any harm, even if tuberculosis and not syphilis was the disease.

DR. TAYLOR had also examined the boy's lungs, and found, he thought, bronchial respiration together with a deposit in the left lung.

DR. SMITH thought that every effort should be made to exclude syphilis, if possible.

DR. THOMPSON thought there was scarcely a possibility of syphilis in this case. It could scarcely be acquired, for the boy was too young, and besides, there was no evidence of such a thing. But even if this child should have inherited syphilis, these symptoms, occurring at this late date, cannot be repaired by mercury and potash given as specifics. The outcome of inherited syphilis in a boy of this age would be scrofula or tuberculosis. Dr. Thompson believed this child had tubercular disease, and that the best thing to do was to let the eye alone. The same questions that Dr. Burnett proposes arise when the patient is suffering from tubercular disease of a testicle, a joint, or an important bone It is not certain that the removal of any of these will prevent further infection Even with carcinoma, which the best pathologists consider local in its origin, the removal of the tumor does not always prevent constitutional infection or even a local recurrence He would not object to giving this patient small doses of mercury and potash, for they might have a tonic effect

Dr Burnett said that although he had not before stated it, as a matter of fact, the boy was put under constitutional treatment as soon as he came to the clinic He took mercury and potash thrice daily for a long time After the doctor had exhausted all the resources of pathology and therapeutics, he was driven to believe that the boy was suffering from tubercular disease

Dr D S Lamb then presented the following specimens

LIVER OF STILL-BORN INFANT SHOWING TWO TUMORS,

a small one involving left margin, the other occupying a large part of right lobe These tumors were yellowish white and firm, presenting a marked contrast to the darker and softer normal structure Spleen was enlarged Blood effused under scalp and also over right cerebral hemisphere, this hemorrhage was probably the cause of death Lungs airless, remaining viscera normal Tumors of the liver in the newborn are of the greatest rarity The tumors in this case suggested sarcoma, but the microscopical examination has not yet been completed Had this child lived for several months, the period of their origin would have been doubtful—possibly would have been considered as post natal

SMALL INTESTINE AND MESENTERY OF AN INFANT BORN AT EIGHT MONTHS, WHICH LIVED TWO DAYS

There was double hare-lip and cleft palate, and it was said that the infant was unable to take any nourishment The intestines were normal, but mesenteric glands markedly enlarged The possible relation of this condition to tabes mesenterica is an interesting question It does not seem possible in this case that the glands could have been infected from the intestine The subject of disease in the fœtus and new-born infants is of such obvious value that it need not be enlarged upon It is very desirable that the investigations now being made in this direction should be continued

A PORTION OF LUNG FROM A MONKEY SHOWING TUBERCULAR CAVITIES

This was a young female, and the mate died of same disease about a week previously It seems that not only do many monkeys in captivity die of this disease, but they die from a relatively small amount of disease

DOUBLE PANOPHTHALMITIS FROM A KITTEN

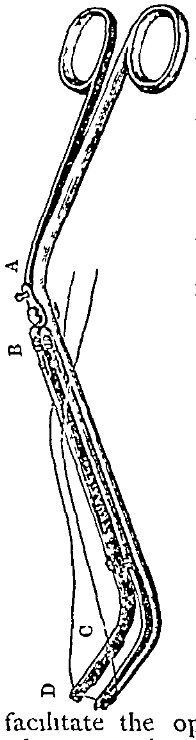
about a month old at death The disease of a week or ten days duration Killed with chloroform and eyes enucleated and placed in alcohol There is a large exudation in the posterior chamber and opacity and staphyloma of the cornea

NEW INSTRUMENTS

A POST-NASAL SNARE APPLICATOR

BY E FLETCHER INGALS, M D

The post nasal snare applicator, to which reference was made in The Journal of December 5, was designed to facilitate the application of a wire loop over tumors in the post-nasal space, and to retain the wire in position until it could be tightened In using it a catheter is passed through the nose, the end being drawn out through the mouth Through this are passed both ends of a wire about three feet long, which are brought out at the nostril The applicator is then attached to the loop, and the catheter and wires are drawn through the nose, the wire loop being drawn back into the mouth As the loop passes under the edge of the soft palate the blades of the applicator are opened, thus spreading out the loop over the tumor The wire loop is then carried by the applicator directly to the base of the growth in the vault of the pharynx, where it is held while an assistant passes the ends of the wire, projecting from the nose, through the tube of a snare, which glides along the wires to the back part of the nares The wires are then fixed to the snare, and by it the loop is drawn tight about the tumor The sliding blades of the applicator are then loosened and the instrument disengaged by a slight movement In the cut, B and D show the sliding blades which retain the wire C in the notches at D A, is a cam which tightens the sliding blades over the notch at D, and which, when turned sideways, allows the blades to be drawn back by the thumb pieces at B, thus releasing the wire at the notches D



The instrument works perfectly, and fully accomplishes the object for which it was designed It is especially useful when the tumor is large, a condition which sometimes makes it extremely difficult to apply the wire loop

For small tumors it is not so essential, but it will be found to greatly facilitate the operation, and to relieve the patient of most of the discomfort incident to the introduction of the fingers behind the palate

64 State St , Chicago, Dec 12, 1885

DOMESTIC CORRESPONDENCE

MALARIAL FEVER AND YELLOW FEVER

Dear Sir —In The Journal of December 5 is an article by Dr de Mello, of Rio de Janeiro, which is designed to show the identity of yellow fever and acute malaria, and which coincides with the ideas I have always entertained in reference to that subject

I was practicing medicine, from 1839 to 1846, inclusive, at the Grand Rapids of the Maumee, in Ohio During the first three or four years of my residence there the Wabash and Erie Canal was being made The termini were the Maumee bay in Ohio, and Evansville in the southwestern corner of Indiana, making it one of the longest canals in the world I am not certain whether a boat ever went through the whole length of this canal The Indiana part of this canal was abandoned a few years ago, and that portion from Terre Haute to Evansville was never used While they were digging the canal in Ohio, nearly all of which I saw, the Maumee Valley got a reputation (and founded on fact) for being one of the most malarious districts in any Northern State, almost vieing with New Orleans A ghastly joke I recollect about Toledo A man inquired the way to Monroe, was told to take the most travelled road, and was brought up at the graveyard Indeed, one summer they were obliged to suspend the work on account of sickness—mostly cases of malarial fever—and many of the pernicious kind Probably it was not so bad as the Panama railway, where, it is said, every tie represents a death, but it was bad enough, as I personally knew after I had been in the country two months In my own case, a few of the results were a spleen about as big as my head, anasarca, and a skin the color of a ripe pumpkin

These sequlæ *might* not have been so bad, had we then known how to treat such cases as well as we now do That is to say, we did not know enough to give quinine in sufficient quantity At that time, the usual treatment was mercurials (principally calomel), tartar emetic, drastic cathartics, and a minimum quantity of quinine—and this must not be taken till the fever had subsided Not often was more than gr ij given in one dose—generally gr x in six doses It is about forty five years since I repudiated the absurd notion of waiting for the fever to intermit before quinine could be safely administered I got a *pointer*, as the boys say, in the practice of a *soi-disant* Dr Sappington (a suggestive name), of Missouri, whose pills nearly always cured malarial fever, and they were to be taken during the fever After this doctor had made a fortune from the sale of his pills, he disclosed the formula, which was nothing but quinine with ext liquorice

But what has all I have said to do with yellow fever? This much, I may say, that I have always considered yellow fever as the gravest form of malarial fever, simple ague being the mildest During my residence in Grand Rapids from 1838 to 1846, I saw many cases every summer of what we called bilious-remittent fever, with intense jaundice, and other symptoms approaching to yellow fever, and in the summer (August) of 1840 I had what might be called a typical case of yellow fever The subject was a laborer on the canal, of middle age, German, who had never been where yellow fever prevailed He had all the characteristic pathognomonic symptoms of yellow fever, including black vomit He died after an illness of three or four days Although I did not *call* this case yellow fever, I never doubted that it was, nor that the cause was there in that canal He was, doubtless, saturated with the poison, whatever that may be, whether it be a microbe or not It followed the "excavations," as Dr Mello said it did in Rio de Janeiro It might be said that I was mistaken in the diagnosis, as I had not then seen a case—but I did afterwards, in New Orleans in 1869, and I know that that man had all the characteristic symptoms of yellow fever, and it would not alter the case, any more than to call a case of small-pox eczema or some other name It would probably take the same cause, essentially, to produce a given effect in the Maumee Valley that it does in New Orleans—though it is true that causes, apparently utterly unlike, will produce effects perfectly identical For instance, I defy anybody to tell the difference between the pustules of varioloid and those produced by tartar emetic And, by the way, I have always believed that pustules produced by tartar emetic *may* be as good a preventive of small pox as the vaccine virus, but, for obvious reasons, I cannot prove it

Whenever there is an epidemic of yellow fever in New Orleans, especially at the commencement, there is generally some dispute among the doctors, as to whether the fevers are yellow, or cases of grave bilious fever, a nice distinction, without a difference except in degree, I think I believe, however, they call these milder cases *malarial*, to contra distinguish them If the microscopic yellow fever germ should be discovered, if it has not yet been, I believe the identity will be shown—till then, I shall think that Dr Mello's theory is the most important contribution on this subject in recent times

PASSAGE OF A LARGE PIECE OF GLASS THROUGH THE FOOT, AFTER FIVE MONTHS

To the Editor of the Journal

Dear Sir —The following case may prove somewhat interesting to the readers of The Journal

William I D , aged 17 years, while swimming on July 2, 1885, cut a deep gash in his right foot on some sharp object in the water The wound was about the centre of the plantar surface of the foot, from side to side, and about an inch and a half from the base of the toes There was considerable hæmorrhage, which was arrested by a companion The wound was completely healed in two weeks, and no physician had seen the case About this time a small swelling appeared on the top of the foot, causing great sensitiveness, on account of which the top of the shoe had to be cut away This was the only inconvenience that the patient suffered, except that when he had been on his foot all day it became tired and somewhat painful He could walk and run without difficulty or limping, and for five months the right foot was used as much as the other

On November 12, the sensitive spot on the top of the foot was accidentally struck, causing great pain and rupture of the skin, giving exit to some blood and pus I was called in on the evening of November 13 Near the surface of the small open wound I found the point of a hard foreign substance, which on probing was found to be of considerable size, and deeply imbedded in the foot Attempts at removal caused such pain that it was necessary to administer chloroform The opening, which corresponded with the space between the second and third metatarsal bones, was enlarged, and with a pair of dressing forceps considerable force was required to dislodge the foreign body, which proved to be a triangular piece of glass, measuring three quarters of an inch on every side, and one-eighth of an inch in thickness It is evident that this piece of glass had been in the foot for more than five months and had passed completely through the member The boy is now recovering rapidly

There are two things that seem quite remarkable to me in this case 1 That a foreign body of this character could pass entirely through the foot between the metatarsal bones without causing more interference to locomotion 2 That such a substance could remain in an organ so much used as the foot, without exciting more inflammation and suppuration

BOOK REVIEWS

Post-Mortem Examinations, with Especial Reference to Medico-Legal Practice By Professor Rudolph Virchow Translated by T P Smith, M D , M R C S , England From the fourth German Edition 8vo, pp 138 Philadelphia P Blakiston, Son & Co 1885 Chicago W T Keener

This small book, as is to be expected from the name of its author, is worthy of careful study The first portion describes somewhat the history of the methods of making post mortem examinations as it has been adopted by Virchow When he became Prætor at the Charite he found that the autopsies were made without method and by many persons who were incompetent He defined a method, which since then he has improved, and instituted a thorough system in the making of all examinations Too much cannot be said in this country upon this subject of pursuing a system in the making of autopsies Few physicians have had instruction in the subject, and when they attempt an autopsy they make bungling work of it If they knew how, many more private autopsies would be made, for it need not be an unpleasant task, and it need not take long In hospitals the autopsies too often are made by students or internes without oversight or guidance As a result, very much valuable material is lost and wasted All physicians and students should study some such book as this, unless they have had the advantage of practical instruction

The remainder of the book is taken up with comments upon and fuller explanations of the rules or "regulations for the guidance of medical jurists in conducting post mortems," which are given in full at the end of the little volume Several cases are fully described as they were made by Virchow These are given both to illustrate the methods of operating and of describing what is seen at the autopsy The description of these cases adds very much to the value of the book

A Treatise on Practical Chemistry and Qualitative Inorganic Analysis By Frank Clowes, D Sc , Lond From the fourth English Edition 8vo, pp 376 Illustrated Philadelphia Lea Brothers & Co 1885 Chicago Jansen, McClurg & Co

The present edition of this well known and extensively used laboratory guide differs from the former issues in slight additions and rearrangements throughout the entire volume The most important of these is the insertion of a section on the analysis of some of the more common organic substances In the introductory chapter there has been a rearrangement, with amplification and the addition of new illustrations for the purpose of rendering the author's instruction more intelligible to the beginner, thus supplementing the work of the teacher or laboratory assistant

A Text-Book of Medical Chemistry For Medical and Pharmaceutical Students and Practitioners By Elias H Bartley, M D , Chief Chemist to the New York State Dairy Commission, Inspector New York State Board of Health, etc Forty Illustrations 8vo, pp viii, 376 Philadelphia P Blakiston, Son & Co 1885 Chicago W T Keener

It is with pleasure that we notice what is probably the best Chemistry for medical students—for its size—now in the market Prof Bartley has written the book because he had something to say, and he has said it well We could wish, however, that under "Ptomaines," some of the methods for searching for these substances had been given in detail Excellent features are a glossary of unusual chemical terms, an appendix giving the analyses of the various fluids of the body, a thoroughly good section on incompatibilities, and a table of solubilities

ASSOCIATION ITEMS

OFFICERS OF THE ASSOCIATION

President—Wm Brodie, M D , Detroit, Michigan

Vice-Presidents—Samuel Logan, M D , New Orleans, La , A Y P Garnett, M D , Washington, D C , Charles Alexander, M D , Eau Claire, Wis , and W F Peck, M D , Davenport, Iowa

Permanent Secretary—Wm B Atkinson, M D , 1400 Pine Street, Philadelphia, Pa

Treasurer—Richard J Dunglison, M D , lock box 1274, Philadelphia, Pa

Librarian—C H A Kleinschmidt, M D , Washington, D C

OFFICERS OF SECTIONS

Section of Practice of Medicine, Materia Medica and Physiology—Chairman, J T Whittaker, M D Cincinnati, Ohio, Secretary, B L Coleman, M D , Lexington, Ky

Section of Obstetrics and Diseases of Women—Chairman, S C Gordon, M D , Portland, Maine, Secretary, Chas T Paine, M D , Comanche, Texas

Section of Surgery and Anatomy—Chairman, Nicholas Senn, M D , Milwaukee, Wis , Secretary, H H Mudd, M D , St Louis, Mo

Section of State Medicine and Hygiene—Chairman, John H Rauch, M D , Springfield, Ill , Secretary, F E Daniel, M D , Austin, Texas

Section of Ophthalmology, Otology and Laryngology—Chairman, Eugene Smith, M D , Detroit, Mich , Secretary, J F Fulton, M D , St Paul, Minn

Section of Diseases of Children—Chairman, W D Haggard, M D , Nashville, Tenn , Secretary, W B Lawrence, M D , Batesville, Ark

Section of Oral and Dental Surgery—Chairman, John S Marshall, M D , Chicago, Ill , Secretary, E A Baldwin, M D , Chicago, Ill

Time and place of Annual Meeting—On the first Tuesday in May, 1886, in St Louis, Mo

Chairman of the Committee of Arrangements—LeGrand Atwood, M D , St Louis, Mo

Assistant Secretary—Wm C Glasgow, M D , St Louis, Mo

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the JOURNAL for one year from the following July Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

RICHARD J DUNGLISON, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

DR W A EAST, of Hallettsville, Texas, died Dec 10, 1885, of pleuro pneumonia Dr East was born in Nashville, Tenn , Dec 9, 1824 He read medicine with Dr Thomas R Jennings, of that city, and attended lectures in Philadelphia during 1845-46 He was for several years Professor of Theory and Practice of Medicine in the Galveston Medical College, and was a member of the American Medical Association, and the Texas State Medical Association He was known throughout his State as one of its best and most conservative practitioners

---

DR ALPERT H SMITH, one of the best known physicians of Philadelphia, and one most beloved by professional friends and his patients, died at his home in that city, on December 14, after a long period of painful illness He was in his fifty-first year

ELEMENTS OF PROGNOSIS IN BRIGHT'S DISEASE[1]

BY AUSTIN FLINT, M D

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE NEW YORK

In the popular mind, the name Bright's disease, at the present time, has a prophetic import not unlike that of a verdict of conviction after a trial for life It is regarded as a hopelessly fatal malady, more hopeless indeed than the condition of one condemned to execution, inasmuch as in the latter case there may be the prospect of a new trial or a hope for pardon This prevailing impression like other popular impressions relating to disease, reflects the views of the medical profession By the latter, Bright's disease, in its chronic form, is generally regarded as a disease from which recovery is not to be expected, a fatal termination taking place invariably sooner or later This view of the prognosis is not far from the truth It may be said, perhaps, to be a view which accords with our present pathological knowledge and clinical experience But the scope of prognosis is not limited to recovery from a disease A disease may involve more or less irremediable damage of important organs, but after having advanced to a certain extent the damage may not become greater, and the portions of the organs which remain unaffected may be sufficient for all the purposes of life and a fair state of health Or, again, a disease may be progressive, but the progress may be so slow as not to interfere with a long duration of life and a certain degree of health A chronic disease may persist, and remaining stationary, life is not endangered by the disease *per se*, but danger may be dependent on associated affections which may, or may not, have a pathological connection with the antecedent disease Or, still again, a chronic disease may be well tolerated indefinitely provided other conditions pertaining to health are favorable, but proving fatal if other conditions, which we may call accessory, be unfavorable These are considerations embraced properly within the scope of prognosis, using this term in its comprehensive sense In this paper I propose to offer some remarks on the elements of prognosis in Bright's disease, taking into view not alone the intrinsic tendency of the disease but the considerations just referred to To be able to foresee the progress and issue of diseases in individual cases, is something more than an interesting professional accomplishment It is of importance as regards the regulation of the private affairs of patients and their friends Of still greater importance is the bearing, often, of prognosis on the treatment of diseases I shall have occasion to refer to some points pertaining to the last named aspect of the subject of this paper

The prognosis in Bright's disease has relation to the form or variety of the disease Is the disease acute or chronic? This question is not always readily answered at the bedside, but I do not propose in this paper to enter into the subject of diagnosis Assuming the existence of acute Bright's disease, experience teaches that, exclusive of important concomitant affections, the disease does not end fatally as a rule, and, moreover, as a rule it does not eventuate in any renal lesion, in other words, the acute is not followed by a chronic form of the disease Exceptionally the acute disease proves fatal, or it continues in a chronic form The points bearing on the prognosis in individual cases, are essentially the same in the acute and the chronic forms These will be referred to in connection with chronic Bright's disease. There are cases of Bright's disease in which the disease cannot with propriety be said to be acute, inasmuch as there are new symptoms denoting acuteness of inflammation, but in other respects corresponding to the acute form The disease in these cases is of temporary duration, and ends in recovery, no evidence of renal lesion remaining These are cases which, as it seems to me, have not received sufficient attention by medical writers

The several designations of acute Bright's disease, namely, acute diffuse nephritis, acute tubal nephritis, acute desquamative nephritis, etc, may be applied to these cases by substituting for the word acute, subacute as distinguished from chronic The clinical history is the same as in the acute disease, except that the symptoms denote a sub acute inflammation, and, anatomically, the disease in these cases differs from the severe forms of chronic Bright's disease in the fact that there is no persistent renal lesion

In a certain proportion of the cases in which acute Bright's disease is said to accompany or follow scarlet fever and other infectious diseases, the inflammation is sub acute Occurring in other pathological connections, or when it is a primary affection, if unattended by œdema of the face or limbs, it is likely to be overlooked by those who do not observe the rule to examine the urine in all cases, whether or not the symptoms point to renal disease. If ascertained, the problem in diagnosis and prognosis is to determine whether the affection be a sub-acute diffuse, or tubular or desquamative nephritis, or whether it be a chronic form of Bright's disease? This problem is not at once easily solved. It can only be definitively solved by the disappearance of all the evidences of renal disease after some weeks, and the recovery of health.

---

[1] Read before the New York County Medical Association November 16th 1885

A diffuse tubular or desquamative nephritis, either acute or sub-acute, not infrequently occurs as an intercurrent event in connection with chronic Bright's disease. The latter affection, prior to the occurrence of the intercurrent nephritis, may have been latent, as regards symptoms other than those pertaining to the urine, and it may again become latent after recovery from the intercurrent inflammation. Here is a problem which cannot at once be definitely solved, namely, whether the existing symptoms such as coma and convulsions, dropsy, etc. are, to a greater or less extent, referable to the progress of these chronic affections, or whether they denote an intercurrent acute or sub-acute inflammation. The bearing of this problem on the prognosis is obvious. The occurrence of an intercurrent nephritis in certain cases explains the development of grave symptoms from which recovery takes place, leaving the patient in the state of health which previously existed.

A practical point, relating to prognosis after recovery from either acute or sub-acute diffuse nephritis, is the existence of a susceptibility of the uriniferous tubes to causes of inflammation. This susceptibility remains after recovery, rendering the patient liable to recurrences of the affection. This holds true whether the nephritis be a primary renal affection, or whether it be developed in connection with chronic Bright's disease.

I proceed to notice some of the elements of prognosis in cases of chronic Bright's disease. The latency in certain cases of Bright's disease for a long period, as regards any important symptoms exclusive of evidences afforded by examinations of the urine, is a most important clinical fact. What are the conditions requisite for latency? *First*, the kidneys must not be damaged beyond a certain extent. Nature has been bountiful in these as in other organs. Inasmuch as it has been demonstrated that one kidney may suffice for the adequate performance of the renal functions, it follows that a lesion may have impaired the functional power of the organs at least one half, without necessarily giving rise to important symptoms of disease. *Second*, the important organs of the body other than the kidneys must be capable of performing satisfactorily their respective functions. The functions of the digestive, the circulatory, the respiratory and the nervous system must be fairly maintained. *Third*, the laws of health, relating to alimentation, exercise, exposure to cold, mental excitement, and habits of life, must be observed. Now suppose, these, as we will call them, accessory conditions to be fulfilled, and a lesion of the kidneys to exist which diminishes their functional ability one-half, and the disease not to be progressive, life and health are compatible with the existence of chronic Bright's disease for an indefinite period. Mark the practical conclusions to which this view of the prognosis leads. In order that a chronic Bright's disease shall be well tolerated, provided the lesion has not reduced the ability of the kidneys to perform adequately their functions, the objects of treatment relate to the accessory conditions required for toleration—to wit, the conditions relating to other organs of the body, and to hygiene. We may assume the necessity for these conditions, inasmuch as the utmost limit of the functional capacity of the kidneys being constantly required, any disturbances elsewhere in the economy will be likely to involve overtasking of these organs. The situation may be compared to that of pulmonary emphysema leaving no reserved capacity of the lungs. Respiration is adequately performed if there be no unusual demand upon this function, but the pulmonary organs cannot meet any extra demand without more or less distress.

A patient comes to a physician complaining of some one of the minor manifestations of uræmia, such as headache, nausea in the morning, misty vision, or of a little œdema of the face and limbs, either with or without uræmic symptoms, or it may be that he complains only of impaired appetite and general debility. An examination of the urine shows the existence of chronic Bright's disease. Now chronic Bright's disease has probably existed in this case for months and perhaps for years. During this period the damage to the kidneys has not been sufficient to render the organs incapable of performing their functions adequately. They who are in the habit of examining the urine in all cases which come under their observation, not infrequently find the evidence of chronic Bright's disease when no symptoms pointed thereto. It may be many months or many years in these cases before the manifestations of the disease appear. I could cite cases illustrative of the latter statement. At length, the progress of the renal affection, or unfavorable accessory conditions, render the kidneys incapable of performing their functions adequately, and then appear symptoms which point to an affection of these organs. Hypertrophy of the heart without valvular lesions, and irrespective of pulmonary disease, is generally a result of a renal affection which must have existed for a considerable period. Now it is not uncommon to find cardiac hypertrophy when there has been nothing to create suspicion of an affection of the kidneys. Again, a person is seized with apoplectic coma and convulsions when apparently in good health. An examination of the urine shows Bright's disease which must have existed for a greater or less period. Instances of this kind have come under my observation.

These facts teach that so long as the kidneys are not damaged sufficiently to render them incompetent to perform their functions adequately, and so long as the accessory conditions which have been referred to are favorable, Bright's disease is well tolerated, that is, the disease is latent as regards any appreciable manifestations irrespective of an examination of the urine. The facts teach, moreover, that if the existence of the disease be known, the objects of treatment are to prevent, if possible, further increase of the renal damage, and to make all the accessory conditions as favorable as possible. The prognosis is favorable in just so far as these objects of treatment are attainable. With reference to these objects the desirability of as early a diagnosis as possible is obvious.

The question now arises, how is the adequacy of the functions of the renal organs to be ascertained, irrespective of any obvious symptoms which are suggestive of inadequacy? The answer to this question, of course, relates to examinations of the urine. Is it an injustice to medical practitioners to say that examinations of the urine often have regard only to the inquiry as to the existence of Bright's disease, and to the form of the disease which exists, overlooking the importance of ascertaining the sufficiency of excrementitious elimination? The latter is the important object of the examinations with reference to prognosis. Are not examinations often limited to specimens consisting of a few ounces of urine, the quantity passed in a given time being imperfectly known, and, perhaps, not made an object of inquiry? The amount of albumen excreted and the number and variety of tube casts are important with reference to the existence and the form of Bright's disease, but it is generally of much more importance to obtain information respecting the adequacy of the renal functions. I have frequently been struck with the fact that in examinations of the urine the specific gravity has not been taken into account. Albumen and casts in the urine show that the kidneys are doing what healthy organs ought not to do, but the more important inquiry is, are they doing what healthy organs ought to do? The kidneys may eliminate in abundance excrementitious products although albumen and casts are present abundantly in the urine, and, *per contra*, the elimination of these products may be more or less inadequate, although the urine may contain little or no albumen, and casts are wanting.

Inattention to the adequacy of the renal functions must be attributable to a lack of appreciation of the importance of this point of inquiry, inasmuch as information respecting this point is readily obtained. It suffices generally to ascertain the amount of urine passed in twenty four hours, and to employ the urinometer. The quantity and the specific gravity are data for a rough estimate of the excrementitious products, but, practically, the estimate is near enough to accuracy. It is certainly not too strong an assertion that to be satisfied with the information that the quantity of urine is normal, without knowledge of its density, in cases of Bright's disease, is a culpable neglect. An apology may seem to be required for saying that the quantity of urine may be much increased, but with a specific gravity so low as to involve great danger from uræmic toxæmia, yet I can recall a case in which, under such circumstances, a practitioner had assiduously striven to lessen the amount of urinary secretion!

The prognosis based on renal inadequacy relates, of course, to the liability to grave uræmic consequences. The object of treatment is to avert these by measures either to increase the excretory action of the kidneys or to promote the vicarious elimination of the urinary constituents, and perhaps, also, to render the system tolerant of the over-accumulation in the blood of these constituents. The last of these three indications I have been led to believe may be in a measure fulfilled by opium, but the discussion of this point would be here out of place. Let it be supposed that notwithstanding the evidences of Bright's disease examinations of the urine afford proof of renal adequacy, what bearing has this fact on the treatment? The indication for diuretics, hydragogues and sudorifics is certainly wanting under these circumstances. I submit the inquiry whether it be not an error in practice too often committed to employ diuretics, hydragogues and sudorifics in cases of Bright's disease when these are not indicated? And, if not indicated, inasmuch as they are more or less perturbatory and debilitating in their effects, they are, of course, contra-indicated. I will cite for illustration a case which has come under my observation since I began to write this paper. A man about 50 years of age, of good habits, but for a long period overworked by his duties as a banker, for the last year or longer had felt a lack of his usual energy and endurance. In other respects he had no special ailments. There were no symptoms pointing to uræmia. He had noticed an increased quantity of urine. Two examinations of the urine showed a specific gravity of 1003 and 1008, and albumen small in quantity in the first, but considerable in the second examination. Casts were not discovered at either of these examinations. The quantity of urine furnished for the second examination had been passed in twenty four hours and amounted to eighty-six ounces.

What were the indications for treatment in this case? There was not renal inadequacy. Diuretics were certainly not indicated. It was probably an object in the treatment to relieve the kidneys in a measure of the burthen of their functions by providing for some elimination by the intestinal canal and the skin, but employing for this object measures which are neither perturbatory nor debilitating. The great objects in the treatment were, evidently, prevention of further progress of the renal affection and promotion of tolerance. I presume that it will be admitted we have no knowledge of any special remedies for the first of these two objects. The treatment, therefore, must have reference to accessory conditions and to hygiene. As regards the prognosis in such a case, it relates to non progression of the renal affection and to tolerance. Under favorable circumstances, life and a fair amount of health may continue for a long period.

Is the degree of renal inadequacy, as determined by examinations of the urine, reliable for judging of the absence of danger from uræmia? This question must be answered in the negative. In some cases of Bright's disease the quantity of excrementitious principles in the urine are notably diminished for a long period without the development of serious uræmic consequences. The explanation is, that these principles may be vicariously eliminated, or their accumulation in the blood takes place without toxical effects because the system becomes accommodated to them, as opium or arsenic may be introduced in large quantities innocuously as a result of their habitual use On the other hand, in some cases a moderate diminution of the excrementitious principles of the urine is followed by serious uræmic consequences, their vicarious elimination being inadequate, and toleration not having been acquired by habit These facts are to be taken into account, in individual cases, with reference to prognosis

The prognosis in cases of uræmic coma incident to chronic Bright's disease is always grave Yet, every practitioner of much experience has met with instances in which the attacks have been severe, prolonged and repeatedly recurrent, without proving fatal This fact shows conclusively that in these instances something is added to the chronic renal affection This something may be an intercurrent inflammation, acute or sub acute, to which I have referred in the first part of this paper, or it may be referable to what I have termed the accessory conditions involved in the toleration of the renal affection The fact, it is needless to say, is of much importance as furnishing a powerful motive for the employment of efficient measures to avert impending danger Of acute pulmonary œdema the same may be said as of uræmic coma In my experience, thus far, of the grave manifestations of uræmia, the greatest is dyspnœa, called by some writers "renal asthma," which is independent of any pulmonary affection, and attributable to a toxical effect upon the respiratory centre in the nervous system I cannot recall an instance among the cases which have come under my observation, in which this symptom has not been the precursor of a fatal termination I have known, however, life with fair health to continue for years after an attack of acute pulmonary œdema incident to chronic Bright's disease, and apparently for a time placing life in imminent danger

In this brief paper I have introduced topics which might readily have led to a much more extended consideration than I have given to them My purpose has been, not to consider these topics as fully as their importance claims, but to offer them for discussion by those present at this meeting In order to allow time for their discussion, I have designedly limited the length of my paper In conclusion, I will recapitulate the points to which is invited the attention of those who are to engage in the discussion

1 Acute Bright's disease, as a rule, does not tend to a fatal result, nor to eventuate in a chronic affection

2 A sub acute diffuse nephritis having the same seat and character as acute Bright's disease, exclusive of acuteness, occurs not only after scarlet fever and other infectious diseases, but irrespective of these Occurring in other pathological connections, or as a primary affection, it is liable to be overlooked, and, if recognized, it is liable to be mistaken for a chronic form of Bright's disease

3 Acute Bright's disease or a sub acute diffuse nephritis not infrequently occurs as an intercurrent affection in the course of Bright's disease

4 A susceptibility to the causes of inflammation of the uriniferous tubes, irrespective of the existence of chronic Bright's disease, is to be recognized as an individual peculiarity

5 Chronic Bright's disease may exist as a latent affection for an indefinite period, provided the danger to the kidneys is no more than an equivalent to the loss of one of these organs, and provided the functions of the other organs of the body are well performed, and provided the laws of health are observed The disease may be well tolerated so long as the renal affection does not progress, and the accessory conditions are favorable

6 The adequacy of the functions of the kidneys has relation chiefly to the amount of excrementitious elimination of these organs, and this amount may be determined with sufficient exactness by ascertaining the specific gravity of the urine and the quantity in a given time If there be not inadequacy, the treatment by diuretics, hydragogues and sudorifics is not only uncalled for but hurtful

7 The danger from the accumulations of the constituents of the urine in the blood is not in all cases determinable with accuracy by ascertaining the amount of renal inadequacy, owing to variations in the efficiency of vicarious elimination and in the tolerance from habit of these constituents

8 Uræmic coma, occurring in cases of chronic Bright's disease, may be incident to an intercurrent temporary nephritic inflammation or to accessory conditions, so that if impending danger can be averted, restoration to the state of health which existed prior to its occurrence may be hoped for This statement applies also to acute pulmonary œdema.

9 Renal asthma is generally, if not invariably, a fatal prognostic

SOME CAUSES OF TARDY FIRST STAGE OF LABOR, AND THEIR TREATMENT[1]

BY ELLIOTT RICHARDSON, M D,

OF PHILADELPHIA

The following cases have been of interest to me, and I trust will be so to others Most of them represent instances of certain forms of dystocia, which are neither new or very rare, and the treatment of which is often a matter of censure to the accoucher

Case 1 —Mrs M, æt 28, born in England, a very light blonde of more than medium height, and apparently well formed, was taken in labor with her first child early in the morning of February 18th 1883 Her previous history was uneventful in a clinical point of view, no evidence having been elicited of any protracted or violent illness, or of hereditary taint of any kind The pains were not at first severe, but became more so as the labor advanced I saw her in the evening of the 18th, when I found the os dilated to about the size of a quarter of a dollar, thin, but soft, and not sensitive to the touch During the pains the bag of water, which was very small, seemed to press but lightly through the os Through the membranes the presenting head was felt in an attitude of semi extension, with the anterior fontanel

---

[1] Read before the Philadelphia Obstetrical Society on Dec 3 1885

occupying nearly the centre of the field The occiput was directed toward left acetabulum The presenting head was held at the superior strait, and did not advance during a pain, but it so closely fitted the lower segment of the uterus as to completely separate the amniotic cavity above from that below, and prevent any addition being made to the small amount of liquor amnii contained in the bag of waters Nor did the head show any disposition to become flexed either during a pain or its absence

Labor continued with moderate pains during the 19th and 20th, with but little effect upon the os so far as could be perceived by the touch, although it was evident that a very slow dilatation was being effected The condition of the patient during this time remained good, and gave no occasion for anxiety or alarm On the morning of the 21st, the fourth day of labor, however, symptoms of exhaustion became apparent The pulse ran up to over 100, and increased bodily heat was associated with a tendency to dryness of the mucous surfaces Still, but little progress had been made in accomplishing the dilatation of the os, which was at this time opened to about the size of a half dollar It was still impossible, without artificial dilatation, to attempt either version or forceps delivery The head had not advanced and still plugged up the lower segment of the uterus as effectually as ever

Two courses were open to me One was to dilate the os artificially and apply forceps or turn, the other was to support the patient's strength by securing to her needed rest, while at the same time promoting perfect relaxation of the soft parts, hoping that sufficient dilatation would, under this treatment, soon enable me to rupture the membranes, when the head, being exposed to pressure from the uterine contractions above it, would fairly engage, and, it was hoped, descend through the os uteri and the superior strait The latter course was chosen, and in order to carry out the treatment a sixth of a grain of sulphate of morphine was given every four hours, while the severity of the pains was still further mitigated by inhalations of chloroform at the beginning of each pain Under this treatment the general condition of the patient improved, she slept regularly between the pains, and in that way got much rest By 10 o'clock in the evening sufficient dilatation had been secured to justify me in rupturing the membranes, when the head descended and soon the second stage of labor was established This terminated successfully for both mother and child at about 11 o'clock that evening Thus was the labor happily and successfully concluded after a duration of about ninety hours, by the use of constitutional means alone

The external measurements of the pelvis subsequently taken with care showed the following dimensions

Between ant sup sp processes	8⅝ inches
Between crests	10⅞ "
External conjugate	6⅓ "
Real conjugate by inference	3⅓ "

The relation of the measurements of the distances between crests and anterior superior spinous processes precludes, almost to a certainty, the existence of a rachitic pelvis, and as all the measurements were somewhat below the normal, the small pelvis was probably one of those in which the sexual development of the pelvis was imperfect, that is, arrested in its progress The attitude of partial extension observed in the fœtal head in the case just given is explained by the fact that the extremities of the narrowed conjugate diameter formed the points of resistance to the descent of the head, and as these would naturally offer much more obstruction to the descent of the greater diameters near the occipital extremity than to the narrower ones near the face, the latter extremity would of necessity descend first In the last day of the labor I had the benefit of the advice of Dr Albert H Smith, who then, for the first time, saw the case with me

Case 2 —On March 25th, 1885, I saw, in consultation with Dr Hampton, Mrs M , in labor with her first child She had been in labor for nearly twenty-four hours without making any great apparent progress On examining I found the os dilated to about the size of a half dollar, and presenting no abnormal conditions The bag of waters was small and did not seem to press with any force through the os during the pains The head presented in the second position, and was held in a partially flexed attitude at the superior strait The patient was much alarmed at the slow progress she was making, so that the pains were becoming very rapid without materially aiding in the advancement of the labor The treatment adopted in this case was rest in bed, one sixth of a grain of morphia every four hours, and inhalations of ether at the beginning of each pain The membranes were ruptured as soon as a greater amount of dilatation had been secured, and twelve hours after I saw the case she was safely delivered of a living child No opportunity was afforded me to measure the pelvis after the termination of the labor

This case differs from the first in degree only, the nature of the impediments to the progress of the labor being the same In both the dilating wedge usually afforded by the bag of waters was wanting, because the closely fitting head prevented access of any considerable amount of liquor amnii to that part of the amniotic cavity which was in advance of it, and the head itself did not advance because it was held at the brim of the pelvis by the narrow conjugate While in normal labor, before the membranes are ruptured all parts of the fœtus are exposed to a like pressure, because that pressure is communicated to it by the liquor amnii, when the head cannot advance, and at the same time prevents any part of the liquor amnii descending past it into the bag of waters, this equilibrium of pressure becomes destroyed, that part of the fœtus which lies above the line of contact of the head with the uterine walls receiving the full force of the contractions of the uterine muscles, while that part which is below only receives the force of resistance offered by the cervix Hence, when the latter is soft and dilatable a process of molding, or adaptation of the presenting part of the head, occurs, during which the most depending part gradually approaches the os and tends to dilate it by affording that dilating wedge which is absent at an earlier period of the labor. When the head, by this process, approaches so close to the membrane closing the os as to exert considerable pressure upon the latter, all further moulding ceases, but at the same time dilatation of the os becomes more rapid, so that soon it will have progressed to a sufficient degree to justify rupture of the membranes. The effect of such rupture is to relieve the head of all impediment to the further progress of moulding and elongation. It is now thrust downward, and if the pelvic narrowing is not great will soon pass through the urine and into the os. The latter being exposed for the first time to the whole dilating power of the uterus, readily yields.

The peculiarity of the first stage of the labor, which in all its important bearings upon the welfare of the woman and fœtus widely distinguish it from the second stage, is that so long as the membranes are intact, the relations of the two beings to each other are precisely the same as those existing during the course of gestation, so that almost indefinite delay is perfectly consistent with the entire safety of both. Notwithstanding this fact the first stage of labor is often a period of great danger to both. The danger to the mother is from exhaustion, and exceptionally from rupture of the uterus, that of the fœtus is from asphyxia, due to the too frequent or too powerful uterine contractions. The mother will only become exhausted when the pains become so frequent, so violent, or so long continued that she is not able to restore her strength from time to time by sleep and perfect rest between the pains. The same condition with regard to the nature of the pains, early rupture of the membranes, and probably some abnormal state of the tissues of the uterus are essential to the production of rupture of that organ. The risk to the fœtus is due to the same condition of the uterine contractions as those which impair the mother's strength, in which the time intervening between the pains is not sufficient for the removal of the vitiated blood from the maternal part of the placental circulation and the supply of arterial blood in its place.

In considering the relations of the woman and fœtus to each other, and the nature of the dangers which threaten each in the first stage of labor, the indications for treatment might seem to be obvious. They are to preserve the proper strength and rhythm of the uterine contractions in order to secure needed rest to the mother, and sufficient regularity in the placental circulation to supply the fœtus with enough oxygen for its preservation. When, therefore, it is obvious that from any cause the dilatation of the os uteri must be a prolonged process, we should take care to protect both the woman and the fœtus from danger during its progress. Even weak uterine contraction may, by becoming nearly continuous, produce the dangers already alluded to, and so while endeavoring to strengthen them, care must be used to preserve their rhythm. In the cases which I have reported this principle was adopted in treatment. Nothing was done until the pains became abnormal in character, when the measures already detailed were instituted. In both cases morphia was used by the mouth, in one case inhalations of chloroform, in the other of ether, were used in conjunction with the opiate. In view of recent experiment there can be no doubt that ether is the safer remedy of the two, and yet it possesses so many disadvantages when compared with chloroform, and the risk from the latter when carefully used in these cases and in conjunction with the use of opium in some form is so slight, that it is a question in my mind whether we are not often justified in using chloroform in preference.

During the first stage of labor, if no painful operation is to be performed, it is not necessary nor even desirable to produce entire unconsciousness. The anæsthetic is given to mitigate pain, not to entirely destroy the consciousness of it, and at the same time to prevent both mental and uterine irritability. Opium and chloroform supplement each other to a great extent, so that when the effects of the two are combined a much smaller dose of each is required to produce a given effect than when either is used alone. This is not so with opium and ether, or to so slight an extent as to be almost inappreciable. While in a woman in labor who is under the moderate influence of opium, but a small amount of chloroform administered by inhalation is sufficient to give all the relief from pain needed. The quantity of ether to be used to produce the same beneficial effect will not be found to be less than when no opium has been given. The practical result of this relation of the remedies to each other is that in the former case the patient's suffering is relieved at once, while in the latter some time is required before any decided amelioration is experienced. In support of the above assertions I may be permitted to quote somewhat at length from the able paper of J. C. Reeve, M.D. of Dayton, O., which appeared in the *American Journal of Medical Sciences* for July, 1880. In the course of his review of Dr. Kappeler's book on "Anæsthetics," Dr. Reeve says: "The modification of the ordinary course of anæsthesia by the preliminary injection of morphia deserves attention. It is claimed for this 'mixed narcosis' that it is especially adapted to prolonged operations by rendering a far less quantity of chloroform necessary, the anæsthesia being continued with far less frequent repetition of inhalation, that the stage of excitement, both muscular and mental, is lessened, and that thereby the dangers of anæsthesia are diminished. Mollow, one of its enthusiastic advocates, goes further, and claims that the action of the morphia lessens irritability of the air passages, and so restrains reflex action upon the heart, that in this respect its effect is similar to division of the *par vagum*, also that the morphia in small doses increases the blood pressure by its action on the motor ganglia of the heart and by its contraction of the peripheral vessels, thereby opposing the chief deleterious influence of chloroform from the beginning by presenting an opposition which must be overcome before the vascular pressure can sink below the normal." As to the smaller quantity of chloroform necessary for a given length of anæsthesia, the less amount of muscular excitement and the modified mental condition, Dr. Kappeler says "the advantages have been on various sides clinically proved, and are only seldom called in question." The advantages claimed by this method have been denied by Demarquay, but confirmed by Heitel, and in part by Konig. The latter does not, however, believe that the dangers from chloroform are at all diminished by the use of morphia. Dr. Reeve further stated that "none of the advantages of chloroform-morphia narcosis attach to ether-morphia narcosis," and that Dr. Kappeler's "experience . . . seems to show that in all respects the combination is injurious rather than beneficial."

Reference is made in the paragraphs which I have quoted to the use of the agents mentioned in surgery alone. They apply in the main to obstetrics as well, although I do not see any disadvantage in theory, nor have I in practice, in the ether-morphia narcosis as compared with ether narcosis alone. In comparing the effects of chloroform and ether in the first stage of labor, the former has, I believe, a decided advantage in its effects upon the os uteri, in promoting relaxation. All the advantages above attached to it are at the same time coupled with its easy and pleasant administration. Against these, however, must be offset the danger from its use. Exactly how great this danger may be in careful hands, cannot be told. In many cases of fatal chloroform poisoning it has been the first few drops that have killed; in such cases, therefore, the diminished amount rendered necessary by the morphia previously given would be no safeguard. I believe, however, that the danger is so infinitely small when thus given that we are justified in using it in painful cases of labor, especially when the chief difficulty lies in the rigid condition of the cervix or other soft parts of the parturient canal, and that in such cases the use of morphia either by the mouth or hypodermically in moderate doses greatly facilitates accomplishment of the end in view. At the same time I would not be understood as advising the use of chloroform instead of ether in ordinary cases of painful labor. Since in these the only object is to relieve pain, ether answers the purpose, and being the safer remedy, should be preferred.

Another cause of tardy first stage of labor is *premature rupture of the membranes*. This accident is apt to interfere with the progress of labor in the stage of dilatation by the absence of the dilating cone formed by the membranes in normal cases, and by direct contact of the presenting part of the fœtus with the uterus. Owing to the former the uterine force is exerted at a disadvantage, and by the latter the os is apt to become rigid, dry and sensitive, while the mother's suffering is much increased. The fœtus is exposed to exceptional risk when obliged to pass through the entire stage of dilatation of the os without the protection of the liquor amnii, for not only are its parts subjected to injurious pressure, but owing to the much greater degree to which the uterus can contract, the interruption of the supply of maternal blood to the placenta is much more complete; yet it is possible for the fœtus to retain perfect vitality for many days after the escape of the liquor amnii, as is shown in the following cases:

Case 3.—Mrs. M., æt. 38, sent for me in June, 1878. I found her pregnant with her eighth child. She was in a state of great anxiety on account, as she asserted, of the escape of the waters which she told me had come away in large quantities. Examination did not convince me of the accuracy of her statement, and I concluded she had mistaken the source of the aqueous flow. One thing was certain, however, and that was that she was not then in labor, although very near her time. She was enjoined to keep quiet, though rest in bed was not insisted upon. Five days afterwards I was again sent for, and found her in the first stage of labor, but no membranes could be felt. She was safely delivered of a living child.

If the membranes really did rupture at the time supposed, this is the longest period between the rupture of the membranes and the coming on of labor I have met with personally, but the following cases represent the possibility of the preservation of the vitality of the fœtus under these unfavorable circumstances for a much longer period. Dr. Matthews Duncan reports a case in the *Lancet*, for June 29, 1872, in which forty-five days elapsed from the time of the rupture of the membranes to that of the birth of the child. During the whole of this period the liquor amnii continued to escape as it was secreted, and the size of the uterus as felt through the abdominal walls was greatly diminished. When labor took place a seven months fœtus was born, and lived for several hours, although much deformed by the protracted pressure to which it had been exposed. In the *Medical Times and Gazette*, for Sept. 18, 1852, Dr. John Gould reports a case in which twins, a boy and girl, were born, living five weeks after the water had come away. Although the above cases are well authenticated, especially that of Dr. Duncan, in which the most careful observations were made, yet the asserted escape of the liquor amnii must be always received with great caution. The sources of the aqueous flow which may be mistaken for the liquor amnii are numerous. The spontaneous escape of urine is not infrequently mistaken by the patient for that of the liquor amnii, while the flow of profuse secretions of Cowper's glands, the rupture of a cyst of the chorion, of another developed or undeveloped ovum, of a cyst lying between the chorion and the amnion, may prove the source of the supposed liquor amnii.

That the membranes may again close after having been ruptured has been proven. This is not accomplished by a process of healing, as was at one time supposed, but by the sliding of the different layers, of which the membranes are composed, upon each other, by which a small opening may be effectually closed. After closure of the amniotic cavity in the manner described, the liquor amnii again collects, for this fluid is continually secreted, as first shown by Winkler, and demonstrated in Matthews Duncan's case.

A source of error in diagnosis as to the origin of the flow is in rupture of the membranes at a point within the borders of the os and out of reach of the examining finger. Here vaginal examination shows the presence of the membranes closing the os, and which become tense during the pains, while the opening becomes patulous and admits of the escape of the liquor amnii during the periods of relaxation. Notwithstanding the occasional occurrence of cases such as I have just given, the usual result of the escape of the waters, at whatever period of gestation it may occur, is to precipitate immediate labor, and this labor, as already shown, is unusually distressing to the mother, and at the same time subjects the fœtus to increased risks. We have seen that the peril to the fœtus is due solely to the persistence or the frequency and violence of the pains, interrupting too frequently, too persistently, or too completely the supply of maternal blood to the placenta.

The abnormal pains are not alone due to the irritation of the mouth of the uterus by the direct contact of the fœtal parts with the uterus, but also to the mental condition of the woman. Most women view the occurrence of rupture of the membranes at the beginning of labor, with anxiety and alarm, and such a state of mind is very apt to be reflected injuriously upon the action of the uterine muscles. Hence care is necessary in the conduct of such labors, first of all to reassure the patient, then to enjoin rest as soon as the pains come on, and, if they are at all disposed to assume an abnormal character, to keep the woman constantly in bed and give opiates to control the severity of the pains, to preserve the proper rhythm of the contractions, and to favor dilatation of the os.

Before closing this paper I wish to refer to another, though kindred, subject. I allude to the obscure symptoms sometimes occasioned in the parturient woman by the presence of intercurrent acute disease. I have several times been deceived by symptoms due to the malarial poison becoming manifest during labor, or in the lying-in period, which have in the one case closely simulated approaching exhaustion and in the other acute local inflammation. Sometimes the manifestations of the presence of this poison consist of chills, followed by fever, while in other cases there is more or less severe neuralgic pain alone. When the previous history of the patient has been obtained, and such history shows the presence of the malarial poison, the diagnosis of the true nature of the symptoms is not difficult, but it is so when no evidence of previous symptoms of intermittent fever is attainable. The following case is one of this character.

Case 4.—Mrs. C., æt. 22 years, was taken in labor with her first child early in the morning of June 8th. As she had been referred to me for attendance in confinement by her regular medical attendant, I had no opportunity of obtaining a personal knowledge of her previous health. I learned, however, that in so far as she knew she had never suffered from malarial poisoning, but she had suffered very much from almost nausea and frequent vomiting at the beginning and towards the close of her pregnancy. The labor continued throughout the day, and in the evening became quite severe. The vertex presented in the first position. As the os dilated but slowly, and the patient's sufferings were severe, I ordered her to take a full dose of morphia. An hour or two later her symptoms were not satisfactory, her pulse was beating at the rate of more than 100, her mouth showed a tendency to dryness, constant thirst existed, and the patient frequently vomited bilious matter. Although the uterine contractions were very painful and frequent, they were short, weak, and inefficient, when the patient had been over twenty hours in labor. As the os was pretty widely dilated, I decided, in view of the symptoms, to apply the forceps and establish the second stage of labor, believing the physical strength of the patient to be sufficient to safely accomplish the subsequent stages of delivery. She was accordingly etherized to complete unconsciousness, and the head of the child brought through the os and down upon the floor of the pelvis. The forceps were then withdrawn. As the effect of the ether passed off good expulsive pains came on, and in due time a living child was born without accident.

The mother did well for the first nine days after delivery, although the frequent pulse continued, with much coating of the tongue and some headache, but without any febrile symptoms whatever. On the tenth day, however, while still kept in bed, she was seized with pain in the left iliac region, which, on the following day, became violent, and did not yield to the small quantity of opium (a remedy which she could not take without very disagreeable symptoms) which I induced her to take. This pain was not accompanied by fever, and I had no doubt was malarial in its origin. Acting upon this belief she was placed upon full doses of quinine, when not only did the pain speedily disappear, but with it the frequent pulse, the headache, and nausea. The patient had come to live in the house in which she was confined but a few months before her confinement, and the first evidences of the presence of the malarial poisoning in her system were those which appeared during her labor and subsequent lying-in. The dryness of the tongue and much of the nausea appearing during labor were probably due to the opium I had given her.

THE ÆSTHETIC APPLICATION OF DENTAL ART[1]

BY W. AUSTIN CURRIE, D.D.S.,

INSTRUCTOR IN CARVING AND PLASTIC MANIPULATION BOSTON DENTAL COLLEGE

On different occasions during my period of practice, I have been requested by patients to explain why it is that dentists seem to know so little about art. What can I say, more than to confess that I do not know? I have found repeatedly that such a reply does not in any sense afford satisfaction to the inquirer, or tend to extricate me from an embarrassing position, but only serves to push me more deeply into difficulties. The query in the outset was prompted, probably, by a passing thought, and had they received any convincing reply, their momentary inquisitiveness would have been gratified and the subject dropped then and there. But, perceiving my inability to give any reason why a profession so entirely made up of artistic requirements, should have no facilities for cultivating an æsthetic taste in the dental colleges, then curiosity naturally became aroused, and I regretted that I allowed them to see that the question was too much for me.

---

[1] Read before the Annual Association of the Boston Dental College Boston October 13 1885.

And can we wonder greatly that such questions meet us, when we reflect that one of the two more important branches of dentistry consists entirely in restoring nature by art? What is Art? Of all the short words in our language there are but few which are handled more frequently, and that, too, by persons who really have but a faint idea of what those three letters signify. How many of the thousands of sight-seers who visit the galleries of our own and foreign countries, and are thus permitted to look upon the work of celebrated artists, comprehend that the creations before them are the result of the careful study of a lifetime. They are only conscious of the general effect of a work of art, and do not realize what a vast amount of study and labor is required to attain such grand results.

For the sake of illustration, let us for an instant glance at a painting. The artist has presented his work true to life, almost too much so to be pleasant. It has been truly said, that, next to the actual pain experienced in being a party to sorrow is the touching suggestion which a faithful picture communicates. Wandering over the canvas, our eye first notes the general interest, we remark the excellency of the drawing, the perspective, and the coloring, but soon our attention becomes riveted on the central object, a representation of an old woman, a glance at whose face at once proclaims the *special* motive of the work. The scene is a court of justice, with all of its characteristic stiffness and its unpleasant suggestiveness. Spectators are there with faces full of feeling. The learned lawyers, in powdered wigs, are there true to life, while, in contrast, stands this poorly dressed woman before the judge who is about to pass sentence of death upon an only son. She is offering a mute appeal—no words of supplication, but the trembling arms and old withered hands outstretched, tears flowing over wrinkled cheeks, the intense agony so plainly depicted on every feature, is an appeal more touching than any eloquence the tongue could have offered. Such a picture commands the attention of every beholder, but how few realize what an immense amount of work it required to reach such a mark of perfection. What an insight into human nature was called for to enable the artist to portray this touching scene. Do they reflect upon the fact that a knowledge of anatomy, physiology, and other studies are required, as well as of colors and their application? Many persons have a faculty of painting a fair representation of the human face upon canvas—they are said to be talented in that respect. But if they expect to approach anywhere in the vicinity of perfection, they must be acquainted with the forms of the bones of the head, as well as the muscles and softer tissues. How can they truthfully give the form of the outside without some knowledge of the framework within.

Now, if this knowledge is indispensable to an artist, why should it not be equally desirable that the mechanical dentist should be conversant with its principles also? An artist, by making himself intimately acquainted with the human form, and by his perceptiveness, power of imitation, and deftness of hand, can place a representation of it upon canvas. He can counterfeit any feature and bring forward any expression. If his work be sculpture, he does away with deception by placing actual shape before us. The one deceives the eye by light and shade, the other gives us substance, the natural light contributing the appearance by which we distinguish the different forms of objects. With the dentist, the object is the same, but, unlike the former, he has not blank canvas or hard stone to work upon, but has living tissues on which he can learn to put different expressions. Many will say that expression comes from the mind, and that we have no control over it except in our own features. True, it comes from the mind, but it shows itself upon the face, and different expressions are but the result of the action of different muscles in moving portions of the skin (and underlying tissues) so that a new light strikes upon it, this varying light, with its consequent shade, adds a new aspect to the countenance.

An artist can change the whole expression of a painted face by the addition of a little extra light and shade, and that with but a few strokes of the brush. All he does is to *apparently* raise some portions with light and cause others to recede by rendering them a little darker. If colors will change the countenance by appearing to raise portions, is it not patent that *actually* raising those parts will do it even better. It takes but the slightest change in position of the lips and adjacent parts to make a great change in expression. You will put greater faith in this assertion if you will experiment a little yourselves. Take a portrait, or, better, two, precisely alike. The lithographs such as are exhibited in the street-windows by theatres will answer every purpose. It will be best if we choose a lady's face, as it is with the ladies' features, principally, that we will wish to utilize our knowledge, if it be found worthy of use. It is, we will say, a full face, and one with a pleasant look about the features. Now with a crayon make a short downward mark from each corner of the mouth on one picture only, as we will need the other for comparison, then with your finger end rub in a little white just under the lower lip, adding a trace of shade to the upper lip in the same manner. What is the result? You have a face the owner of which you would think had not an earthly friend. Now, after erasing what you have added, reverse the order of things by placing the light on the upper, the shade on the lower, and drawing your lines upward from angle of mouth, instead of down, as before, and you will find the result reversed also; for the face is found now to be bright and cheerful. By going a little further, and placing two curved lines from base of nose downward, past corners of mouth, with convexity outward, you have a grin that will often prove contagious. A thin piece of paper placed under the lip on the alveolar ridge, will add its quota to the expression.

These changes have been effected by a few marks that would be hardly noticeable anywhere else on the drawing, unless about the eyes If this can be done on paper, can it not be accomplished, say in part, at least, with the face itself? Of course, it is an entirely different matter when we come to put our theory into practice, as it will require that we educate the eye by long and close observation of nature, and teach the hands to follow its dictates The lips, of all the features, are the most direct index to the feelings, and the expression characteristic of every face is due almost entirely to the effect of light and shade about the lips It is (I believe) because we forget this fact, that we often feel dissatisfied with our work even when the patient expresses pleasure with it I believe, too, that it is owing to the fact that the profession shows want of knowledge, care, or ability in this respect that we meet with so many faces whose owners wear features that are blank, or almost expressionless about the mouth When we hear such common expressions as a beautiful smile, or eloquent lips do we ever ask ourselves in what does this beauty or that eloquence consist?

Our course of studies in mechanics is, to the best of my knowledge, perfect as far as it goes, but is it carried out to its greatest extent? For instance, we are told to carefully note the play of the lips over the wax articulation, but *what is it* in the play of the lips that we are to study? I can but answer for myself I was expecting to hear *expression* treated in every detail, and felt disappointed when, upon nearing a situation where I felt genuine interest, I found that the points which seemed to me of the utmost importance were passed over with a casual remark or two I know when I say this that no one will infer that I am trying to pit my limited knowledge and experience against years of practical work of my instructors Perhaps our teachers expected the students to understand without further instruction Perhaps my classmates, by superior ability, were enabled to bridge over what seemed to me a break in the most interesting part of our course, or it may be that I am expecting too much of dentistry

Now, the question is, how to proceed in order to derive any professional benefit from the ideas here suggested As I regard it, the first requisite is to study nature, and study closely As far as the human countenance is concerned, no one has more opportunity for observation than the dentist Our business carries with it a certain license, so that we can examine a patient's features critically without giving offence Unlimited chances are thus offered, and we can watch every face that we work over, and then we must analyze what we see

Note the general expression, the fulness of the lips, and the tooth development beneath them Watch where and how the light strikes the face, and what is the result of different lights upon the same features If any teeth are absent, note the effect upon the expression Observe color of hair, eyes, and complexion, and then examine the exact shade of the teeth, also the size and shape of the teeth as compared with size and shape of features, form of head, and general build of body This can be done by a trained eye, while the patient undergoes the usual examination without suspecting but that your undivided attention is given to the teeth Then compare this with the next face that presents itself If this is to afford any benefit to the practitioner, the observation and comparison must be critical We are too apt to bestow a casual glance, and forget as soon as the patient is gone, whereas we should memorize or make a note of the most important points

To make ourselves *masters* of the art of light and shade, we must go even further than this *We must cultivate a tast for art* We subscribe for some one or perhaps all of the dental journals—why not for an art journal as well? We try to keep ourselves posted on all the new ideas in our profession—why not mix up a little art with them? Suppose that we cannot see at first that it is benefiting our work, we cannot deny that it is refining, as well as affording a pleasant change from an occupation that is in many respects disagreeable Then when we have leisure we can turn our hands to a little modelling

If we have a small space in our laboratories, why not utilize it by making a bench in a corner that has a good light, and then investing in a few pounds of artists' clay and one or two modelling tools By an hour's work and the outlay of a few dollars, and we have a way of passing our spare moments that will be novel and instructive For it is in modelling and casting that the effect of light and shade is made most manifest If we have doubts of our ability to reap any benefit from modelling, why not try casting choosing a friend or a patient's face for a subject? Suppose that we try it in this way, our subject being a person who wears a full denture and with a bare face? First make a mould of the face (wax will answer) with the mouth empty Then one with the plates in position, and then, after building up with wax in different places on the plates, place them in the mouth and make a third mould Now to cast with plaster The wax mould will of necessity be thin, so that it is best before casting to build up around the outside of the mould with sand so that the weight of the plaster, when soft, will not change the shape Then if you will tint the water with powdered or dry umber and a little vermilion before you mix the plaster, the latter will more nearly resemble the flesh color After casting all three, and allowing the plaster to set, if you will remove the wax from each you will be surprised at the entirely different expression on each face The question is, where you will find a person who will submit to so much trifling? I have experimented with many different faces, and thus far they have been so deeply interested in the novelty of the work that I have yet to meet the first complaint In conclusion, let me say that I believe that if dental practitioners who have never tried this, would do so, they would be surprised and pleased with its effect upon their laboratory work At first, I became discouraged, and thought that I failed more often than I succeeded, but now, when I look back I find that I have not failed On the contrary, I have succeeded so far that now I am where I can see what can be accomplished if one is perseverant I am convinced that the study of facial expression has helped me wonderfully, and has given a new impetus to work that before seemed monotonous One thing in which I think all will agree with me is this, that a little art cannot injure us in any way, even if it is æsthetic

Cambridgeport, Mass , Oct 13, 1885

AN ADDITIONAL CASE OF ACUTE PHTHISIS—QUICK CONSUMPTION—RECOVERY

BY P C JENSEN, PH C, M D,

OF CHICAGO

Mrs A , age 27 years, married, mother of two children Family history of phthisis on mother's side Lost one brother of pulmonary tuberculosis, at 23 years of age, about one year ago The appearance of Mrs A when first seen by me was that of extreme emaciation Her anæmic and debilitated condition gave her a dull and sallow expression, exhibiting with marked distinctness that peculiar white pearly and glossy appearance of the sclerotic, and ocular conjunctiva so characteristic in phthisical subjects

The patient had suffered considerable loss of strength from a long-existing menorrhagia, to such an extent as to reduce the inter menstrual period to ten days During this inter-hæmorrhagic interval she suffered additional exhaustion from a profuse leucorrhœa She was troubled with a severe cough, worse in the afternoon, and continuing until after midnight She expectorated large quantities of yellowish green, tenaceous, but putrid matter

Toward morning she saturated her clothing with a profuse and debilitating perspiration Her temperature reached 102° in the afternoon, but was subnormal in the morning Respiration was bronchial in character, 32 per minute Pulse 140 She experienced a great deal of pain in her left side, and suffered from an almost continued vertical headache Excessive coughing induced at times a reflex nausea

There was decided bronchial respiration in the left lung Increased vocal fremitus and a variety of dry, moist and crepitant râles were audible over the superior anterior two thirds, and superior posterior one-half, of her left lung Right lung not affected The patient had no appetite, her bowels were constipated, and her vital powers greatly exhausted, due to destructive retrograde changes instituted within the pulmonic tissue

By active therapeutic interference, consisting of tonic, nutritive and restorative treatment, and by the administration of remedies having antiseptic influence over pulmonary retrograde processes, also by the additional salutary effects afforded in checking exhausting discharges, viz menorrhagia, leucorrhœa, and night sweats, the patient soon gave evidence of improvement, and before long was convalescent Each case demands a therapeutic difference in treatment, according to the stage of the disease, the peculiarity of the local lesion, its symptomatology, complications, etc , and therefore such variation should consist in the prudent administration and application of rational medicine, so that each remedy shall meet a certain, definite indication

Each case must be treated upon its own merit For the menorrhagia and night sweats ferruginous preparations, ergot and belladonna were given in combination after meals, iodoform for its local antiseptic effect upon the lungs Nux vomica, maltine, digitalis, comp syr of hypophosphites, etc , were administered for their tonic, nutritive and restorative influence The patient is restored to a condition of healthfulness, with no apparent symptoms of return of her disease November 15th an examination revealed normal vesicular respiration She has no cough, no pain, has gained ten pounds in body weight in the last thirty days She is doing her own housework

It must be remembered that there exist various forms of consumption, which differ clinically Each case therefore requires a difference in treatment Again, in the same case there is a development of symptoms forming stages of the disease, each stage demanding its own treatment Some forms of phthisis if not too far advanced, admit of recovery Other forms, especially well advanced cases, speedily or slowly run on to a fatal termination Pulmonary therapeutics, by means of the Pneumatic Cabinet, can be efficiently applied directly to the respiratory mucous membrane of the air vesicles, with beneficial results, in connection with the medical treatment

Room 508, Chicago Opera House, Chicago

OSSIFICATION OF THE CHOROID[1]

BY LYMAN WARE, M D

OF CHICAGO ILL

Although calcareous formations within the eye are of frequent occurrence, osseous formations are not so common but that the following case may be instructive both pathologically and clinically For a long time all hardened deposits in the eye were considered calcareous, and the formation of true bone was much doubted Knapp collected and studied quite a number of cases of ossifications within the eye, which he published in the *Archives of Ophthalmology and Otology*, Vol ii, pp 1–35 At that time he considered the capillary layer of the choroid the origin of all intra ocular ossifications Since then a number of cases have been reported (Knapp's *Archives of Ophthalmology*, Vols vi and ix) in which they occurred in other structures

The formation of bone is usually preceded by prolonged and frequently severe intra ocular inflammation, and is generally of traumatic origin The development of bone requires no other antecedent condition than a vascularized connective tissue

The following is a brief history of a case that came under observation Mr J D, farmer, æt 20, of American birth, when 9 years of age was struck accidentally in the right eye with the handle of a pocket-knife, which completely and instantly destroyed vision, and caused severe inflammation in and about the eye, accompanied by great pain and much distension of the ball and surrounding tissues This continued for several weeks During the five or six subsequent years the injured eye caused little or no trouble During the winter of 1875 and 1876, when he was 16 years of age, or seven years after the accident, as a result of severe exposure the injured eye again became painful, at times better, at times worse Pain usually subsided in a few days if the patient remained quiet in a darkened room, and made frequent hot applications to the eye In the winter of 1880, left eye began to be somewhat sensitive to light, particularly to artificial or light reflected from snow

---

[1] Read before the Chicago Society of Ophthalmogy and Otology October 13 1885

The patient was first seen in July, 1880 The R or injured eye was somewhat atrophied, tension greatly diminished, and slightly tender on pressure, although not markedly so In the L eye there was photophobia, lachrymation, slightly sluggish pupil, and supra-orbital neuralgia Vision for the distance tolerably good (V $= \frac{15}{20}$), but it was quite impossible for him to read even Jæger No 11 more than a minute or two on account of the lachrymation and ciliary neuralgia which it induced Ophthalmoscopic examination showed well marked neuro retinitis

I advised immediate enucleation of the injured eye, but it apparently gave him little trouble, being only slightly painful at times, and as he was a farmer, he did not like the idea of wearing an artificial eye and submitting to all the inconvenience such an eye entails He declined to submit to the operation and returned nome In the latter part of August, five or six weeks after his first visit, he returned to the city and was quite willing to submit to the enucleation of the injured eye, as his symptoms had grown much worse after reaching home Tenderness on pressure of R eye was much increased, and the eyeball intensely injected In the L eye considerable pain and supra orbital neuralgia, sluggish pupil and photophobia V $= \frac{10}{20}$

August 20, 1880 —Patient advised to remain quietly in darkened room and take the following

℞ Dover's P grms 2
Quinæ Sulph 3
Div in cap No 20 S One every four hours

August 24 —Inflammatory symptoms not so great, ether was administered and the injured eyeball removed, although with some difficulty, owing to its atrophied condition, and the dense fibrous adhesions which completely surrounded it

August 25 —Patient fully recovered from the effect of the ether, and the ciliary neuralgia less than it had been for months Ordered pil proto iodid hyd (gr ¼), one three times daily

September 10 —Wound nearly healed, neuralgia entirely absent, vision much improved ($\frac{15}{20}$), and patient allowed to return home, but advised to take the following alterative for six weeks or two months

℞ Pot Iodid grms 16
Tr Cinchon rub 20
Syr Sarsap Co 14
M
S A teaspoonful three times a day, in water after meals

December 4 —Patient returned to the city for artificial eye, no recurrence of neuralgia and vision fully restored (V $= \frac{20}{20}$)

The eye was placed in Muller's fluid for several weeks, then in absolute alcohol, and after three months was partially divided in its equatorial diameter The vitreous was liquefied and immediately escaped, leaving the retina in the form of a cord extending from the fundus or posterior portion of the ball to the anterior, where it expanded funnel like and enclosed a calcareous lens The ossification was situated in the choroid, its thickest portion corresponding with the entrance of the optic nerve

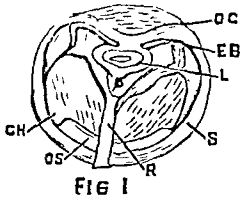

FIG 1

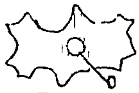

FIG 2

FIG 1 —Antero posterior section of the eye *OS*, ossification *R* retina passing through it and cord or funnel like extending forwards to the calcareous lens *S* sclerotic *L* lens *CH* choroid *CB* ciliary body *OC* opaque cornea
FIG 2 —Ossification (full size)

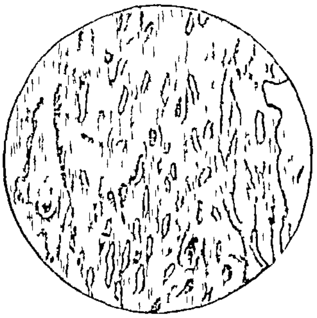

FIG 3

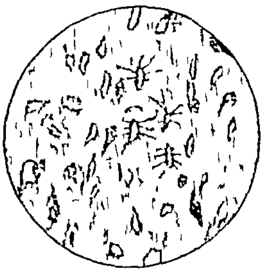

FIG 4

FIG 3 —Microscopical appearances with No 4 object glass
FIG 4 —Appearance under No 10 immersion lens

The eyeball was somewhat atrophied, measuring a trifle over two centimetres in the antero posterior diameter, and a little less than two centimetres in its equatorial axis The ossification measured fifteen mm in length, concavo convex, the concavity looking forwards, and from four to eight mm in width Measured from the optic disc it was a few mm longer on the outer than on the inner side Its greatest thickness, which was at the optic disc, was two mm The posterior or convex surface of the bone was well marked with choroidal pigment Five years have now elapsed since the enucleation, and no relapse has occurred in the eye sympathetically affected

The points of special interest in the case are the slight tenderness in the eye primarily affected, the rapid and complete recovery, and restoration of perfect vision after the injured eye had been removed The question arises, if in cases of sympathetic ophthalmia neuro retinitis be the predominant symptom, is not the prognosis more favorable than when cyclitis predominates? Which nerves are principally concerned in the former and which in the latter?

This case is certainly confirmatory of the conclusion arrived at by Knapp (*Archives of Ophthalmology and Otology*, vol ii, p 34), that "the diseases which lead to ossific productions are chronic inflammations of the interior coats of the eye called internal ophthalmia by the earlier, irido choroiditis by modern writers"

MEDICAL PROGRESS

JEJUNOSTOMY.—At the meeting of the Clinical Society of London, on Nov. 27, MR. C. H. GOLDING-BIRD related the case of a man, æt. 46, who had had symptoms of pyloric obstruction for ten months. When admitted into Guy's Hospital, a tumor could be felt at the seat of the pylorus, and the man's general condition was one of extreme emaciation through the inability to retain the food he took, and his voluntary abstaining from eating on account of the pain he suffered. After three weeks treatment, under Dr. Carrington, by drugs and washing the stomach out, he passed into the author's hands, and when all the risks had been explained to the patient, and all methods of palliation had failed to improve his condition, arrangements were made to explore the diseased parts, and remove them if expedient. He therefore, on October 25, 1885, cut down on the pylorus with a view to performing pylorectomy, following the lines laid down by Billroth; but, finding the tumor adherent to the liver, determined to go no further in the radical operation, but to convert it at once into a palliative one of opening the jejunum, in other words, of performing jejunostomy. Having seized the jejunum two inches from the duodenum, it was held upon a pair of tongue forceps, whilst the wound in the parietes was united; to the lower or right end of this wound was the jejunum now stitched by interrupted sutures. The patient suffered in no way as the result of the operation. He was fed partly by rectum, partly by the mouth, until the third day, when the bowel was opened and food administered solely through the fistula. It was observed that, as long as the meal amounted to a pint, or nearly so, the patient each time he was fed had a severe attack of indigestion, but that this ceased when the meal did not exceed ten ounces. On this the author founded the suggestion that some cases of indigestion were due to the pylorus allowing too free passage of chyme, rather than to anything wrong with the gastric or pancreatic secretions. Everything went on perfectly well till the ninth day, the patient putting on flesh, but on that day, through an error in feeding him, some food passed into the peritoneum, and he died in twelve hours. The post-mortem showed such adhesion to, and infiltration of, the liver, from the cancerous pylorus, that pylorectomy could not have been performed. Except the narrow track made by the probe, and along which the food passed into the peritoneum, the adhesions of the bowel and parietes were perfect. The author than reviewed the operation of pylorectomy, speaking in favor of it in suitable cases, and the operation of gastro duodenostomy, as performed by Wolfler, and pointed out the great drawback, in this operation, that the stomach was not relieved of its physiological duties at all, the pylorus not being required to act. For the operation of jejunostomy, as he termed the one that he detailed, he claimed that, whilst it possessed the same disadvantage as gastrostomy, in that the patient had to be fed through the fistula, it was otherwise the best palliative operation for pyloric cancer, inviting less risk than gastro-enterostomy, and requiring less interference in its performance with the other viscera. By duodenal digestion, he also pointed out, full nourishment could be assured, and there was for physical reasons less chance of regurgitation of food than after gastrostomy, regurgitation in these cases being a serious drawback to that operation in œsophageal constriction.—*Medical Times and Gazette*, December 5, 1885.

CONTRIBUTION TO THE STUDY OF MORPHIOMANIA.—DR. MARANDON DE MONTYEL summarizes the results of his investigations of the production of morphiomania as follows:

I. Morphiomania has its origin either in a demand for intellectual excitation and psychical pleasure or in the acquired habit.

II. Injections of morphia have as a result a double action: a benign and a special action upon the nervous system by which its natural function becomes impossible after a certain term without the assistance of the poison. These two effects are separate and distinct from each other; the second is manifested when the first is no longer exhibited. There are, then, two kinds of morphiomania; the one resulting in temporary good effect, the other a vital necessity; and after a variable period the cases of the first order pass over into the second.

III. This double action of morphia upon the nervous system renders it an extremely dangerous medicament, and it therefore should not be prescribed hypodermically except in cases of absolute necessity.

IV. It is also extremely dangerous to combat morphiomania by the substitution of alcoholics, inasmuch as chronic alcoholic insanity may result therefrom.

V. Morphiomania may always be treated by abrupt withdrawal of the drug, except in conditions when such methods are contraindicated by the vital forces of the patient or concomitant pathological phenomena. The method should also be abandoned if reactionary collapse result.

VI. In the treatment of morphiomania by gradual suppression of the drug, it appears advantageous to combine with the progressive diminution of the dose the recoil of momentum by fusing two injections into one.

VII. The medico legal questions pertaining to morphiomania are certainly based more upon extra-judicial than upon judicial clinical observation.

VIII. Observation shows that a morphiomaniac may have great energy of will while the poison has not yet determined any disorder of intellect. There is here a serious proof of what has already been said, that responsibility only ceases with the period of psycho physical marasmus.

IX. Relative to the responsibility of morphiomaniacs who commit crimes or offenses to satisfy their passion, it is, perhaps, necessary to distinguish whether they have yielded to the simple appetite for a pleasant effect or to a physical necessity dependent upon the instinct of self-preservation. A conclusion of irresponsibility in the latter case seems justified.

X. In the exact appreciation of the intellectual troubles caused by the abuse of the hypodermatic injection of morphia, it is important correctly to appreciate the existence of predisposition to insanity, and the delirium produced concurrently by the absorption of other substances, such as alcohol and belladonna

XI It is necessary to retard the continual progress of morphiomania by disseminating general information in the upper ranks of society concerning the deplorable and certain evil effects following the use of the drug, and to exercise an active surveillance over pharmacists, and impose special penalties upon those who dispense morphia without a physician's prescription —*L'Encephale*, May and June, 1885, *Amer Journ of the Med Sciences*, Oct , 1885

BACTERIOTHERAPY —In a recent number (*British Medical Journal*, August 29, 1885), we gave a short account of Professor Cantani's experiment in "bacteriotherapy," in which a phthisical patient was subjected to inhalations of bacterium termo The result was that bacillus tuberculosis disappeared, and the condition of the patient was wonderfully improved Dr Salama, of Pisa, reports another case of the same kind In a case of phthisis, with a cavity in the apex of the left lung, and various patches of consolidation, Koch's bacillus disappeared within about a fortnight after the inhalations of the bacterium termo were commenced, all the other symptoms improving at the same time Dr Maffucci, Professor of Pathological Anatomy at Pisa, who verified the diagnosis, prepared the bacterium culture A few drops of spring-water were added to a sterilized solution of gelatine in meat broth with peptone After a day or two, colonies of various micro-organisms made their appearance, and amongst them was the bacterium termo Under the microscope, a sterilized platinum needle was dipped into this, and then introduced into another portion of the gelatine preparation After two days, this was found to be a pure culture of the bacterium termo The contents of one test-tube prepared in this way served for one day's inhalations, being mixed with a meat broth made from 150 grammes of beef to 200 grammes of water, and left for eight or ten hours, according to temperature If left too long the putrefaction became insupportable to the patient Broth so prepared was given by Siegel's spray producer every day in divided doses Sufficient time has not yet elapsed to show whether the improvement was permanent It is not quite certain that the bacterium was the sole agent of amelioration here It is possible that the meat-broth may not have been without its effect, and it is just within the range of supposition thar the bacterium has a psychical influence on physician as well as on patient, not less important than its alleged bacillicide properties —*Brit Med Journ*, Nov 28, 1885

A NEW ANTISEPTIC —Those of us who use iodoform in the consulting-room must frequently have been seriously annoyed by its powerful and persistent smell Drs Silber and Ciammician, of Rome, have found an admirable substitute which has all the advantages of iodoform without its odor or, it is said, its poisonous properties This substance is iodol, which occurs as a dark powder with a slight scent, reminding one of thymol It is very slightly soluble, and is best used either in substance or suspended in glycerine, or made into an ointment with vaseline A lotion can also be made by dissolving 1 gramme of iodol in 16 grammes of alcohol and adding 34 grammes of glycerine Most brilliant results have been obtained by the use of the substance itself on chancres and syphilitic adenitis In simple indolent ulcers, too, the use of the iodol lotion has been very beneficial A spot of lupus on the leg was treated by injections of iodol solution into the surrounding subcutaneons tissue with the result of preventing the disease from spreading Iodol has also proved useful in fungating joint diseases Over 200 observations have been made, and neither erysipelas nor a diphtheritic condition of wounds has occurred —*Wiener medicinisches Blatt* —*Medical Times and Gazette*, December 5, 1885

THE APPLICATION OF NAPHTHOL TO SOME FORMS OF CUTANEOUS DISEASE —P SOMBRET (*These de Paris*) gives the following *resume* of the advantages possessed by naphthol in the treatment of some forms of skin disease

1 The preparations are odorless, and stain neither the skin nor clothing

2 In the use of naphthol, with the precautions advised by Kaposi, there are observed neither forms of intoxication (albuminuria, coloration of the urine) nor active inflammation of the skin

3 In scabies, naphthol is an excellent parasiticide and exercises a very beneficial effect upon the eruption due to the disease

4 In pediculosis the remedy is efficacious, and its use is free from danger and inconvenience

5 In psoriasis no satisfactory effect has been observed

6 In prurigo (of Hebra) naphthol causes the itching to disappear rapidly, and has beneficial effect upon the eruption It, nevertheless, does not possess a curative power in this disease greater than that possessed by other remedies —*Revue des Sciences Medicales*, July, 1885 *Amer Journ of the Med Sciences*, Oct , 1885

PELLETIERINE IN OCULO-MOTOR PARALYSIS —The Paris correspondent of the *British Medical Journal* writes that MR GALEZOWSKI recently read a paper before the Académie de Médecine on the action of pelletierine on the motor nerves of the eye His researches are based on the ocular disturbance which occurs in subjects who absorb pelletierine, they are affected with diplopia The observance of this fact induced M Galezowski to prescribe pelletierine when there is paralysis of the third and sixth pairs Iodide of potassium and blisters have failed where pelletierine has cured, the preparation used is syrup of pelletierine, 1 gramme per 120 parts of syrup From three to six doses were administered Unfortunately, this substance is excessively dear M Galezowski hopes to meet this difficulty by administering pelletierine in subcutaneous injections

THE STUDY OF MEDICINE AS A MEANS OF EDUCATION

Such is the title of a paper read before the American Academy of Medicine, at its recent meeting in New York City, by DR J LOWRY SIBBETT, of Carlisle, Pa The paper is not intended, as might at first be supposed, to show that the study of medicine is a means of education, but to show that the preliminary education (or the academic) for the study of medicine should be more thorough, and that this should be insisted upon by the medical colleges

It will be remembered that one of the requirements for membership in the American Academy of Medicine is that the applicant must be a graduate of an academic college, and unless we have misread the article now under consideration, this idea runs through it as an undercurrent, though the author does not express the view that graduates of academic colleges should be admitted to the medical college classes on the face of their diplomas in arts Nevertheless, it is directly implied that a man is unfitted for the study of medicine until he has completed a course (obtained a liberal education) in an academic college Completing a course in an academic college means only that the student has attended recitations or lectures on certain prescribed studies, he has, to quote our author, "studied mathematics, languages, rhetoric logic, mental and moral philosophy, and as much chemistry, geology and astronomy as is usually taught in respectable classical schools" We may assume, says our author, that the medical students from these schools "have spent five or six years in these several departments of useful study, that they have the mental discipline resulting from mathematical demonstrations repeated a thousand times, so important for the development of the reasoning faculties, that they have enjoyed the advantages of analysis and synthesis in the study of languages To all such we would say that they have laid a solid foundation upon which to add professional studies Their education has been in all directions, not merely one class of mental faculties, but all have been exercised and disciplined"

It will be observed that nothing is said in the above quotations as to the value of the sciences in training the mind, or mental faculties, which seems to imply that the sciences (three of which are mentioned) are to be studied solely for a general knowledge of certain facts, and because they are included in the college curriculum It should be remembered that we are now considering the academic "education" as preliminary to the study of medicine particularly Our author speaks of the importance of the study of mathematics for the development of the reasoning faculties, of the study of languages for analysis and synthesis, but does not even allude to the great value of the study of chemistry or geology for these purposes It must, however, be unhesitatingly asserted, that the study of chemistry (a branch, be it remembered, of surpassing importance for the understanding of medicine) *as it should be taught*, far surpasses the study of mathematics for training the reasoning faculties The modern mathematics is of but little value for this purpose, as was pointed out by Whewell more than forty years ago While mathematics is a purely deductive science, it is not yet the embodiment of pure deduction There is no appeal to observation, fact or induction It does not teach the student to, or *how to* observe, generalize, classify, or define by the examination of particular things, and when statements and arguments are confused and perplexed by verbiage, contortions, inversions and ellipses, its principles are absolutely useless In regard to the peculiar advantages of languages for elevating the qualities of synthesis and analysis it may be asserted that they do not exist Language should be studied chiefly as the tool of thought "The scientific student must no longer be handicapped by a linguistic (I will not say literary) burden" (Huxley) The languages now required by a scientific man are English, French, German, and to some and an increasing extent, Italian He does not need them except as tools, to find out what is going on in the scientific world But in order to learn them for this purpose he need not lumber up his memory with a mass of grammatical detail It should be distinctly understood that the literary man may use the results of science as so much literary material without troubling himself as to the methods by which they are arrived at, and that the converse is almost literally true of the scientific man as regards languages

That it should still be held, almost at the close of this century, when the natural sciences are the great powers of the world, and, after religion, the greatest power of modern civilization, when all the ancient and classical learning has failed to stay one human pain or to lift one ounce of human suffering, that the man who has not had the usual routine academic education is unfit for the study of medicine, is beyond conception The whole success of the physician must depend on the skill with which he can utilize the experimental sciences Should the millenial day come when everyone who elects to study medicine must go through a thorough preliminary course of training for it, it is to the experimental sciences that we must look for the foundation upon which to build a thoroughly competent physician And then will come the time when the original investigator will be a usual product, not an accident If the physician is to be scientific, he must have a scientific foundation, but as the case now stands, very few of the graduates of the strictly academic (and most of our academic schools are "classical" schools) of this country are properly prepared for the study of medicine And while we would not decry these schools, it must be said that the instruction given in the greater number of them is not that which fits the student for the study of science, or of a profession founded on science "An instructor in natural science has very much the same difficulty in training classical scholars to observe that a dancing master would have in teaching Chinese girls to waltz" (Cooke)

Medicine, which a century or so ago was ruled by authority and traditions, and might then have been classed with the literary professions, has now come to rest on a purely scientific basis This truth is not altered by the fact that medicine is not yet a pure or exact science And inasmuch as a distinction must be made between literary and scientific professions, an equal distinction should be made in the systems of education that lead up to these professions It is the object of the physician to unravel the mysteries of the healthy and diseased human frame, and to direct and aid the forces of nature for the cure and prevention of disease, and all the logic of the schoolmen, the ability to analyze and read all the Greek and Latin that has ever been written, and the facile demonstration of an epicycloidal curve or of the square described on the hypothenuse of a right angle triangle, are of infinitely small value for these ends as compared with a thorough knowledge of chemistry alone As there is a difference of subject-matter between a scientific and literary profession, there should and must necessarily be a difference in methods, spirit and aim of study

It has been held that Greek scholarship is impossible for the student who begins that study in college, and still less can we expect scientific scholarship when the study of science is first begun and too soon ended in the medical college A change from classical to scientific studies at the age of 18 or 20 has as many disadvantages as changing a profession at 50 However desirable it might be for a man to be both a classical and scientific scholar, he is the rare exception who can attain to this double culture, and as we can neither change the mental capacity nor alter the span of human life, we must be content to strive after that education, that culture, which will make us the most useful citizens If the school men contend that the classical scholar is more brilliant and ornamental, so be it So is the diamond more brilliant than coal, though both are carbon—as are classicists and scientists human And to attempt to make a scientific man in a classical retort is as absurd as to try to make coal a jewel by setting it in gold, or to run a steam engine by throwing diamonds into the furnace In a word, scientific culture is a suitable basis for a liberal education, and it will be recognized as such when the school men cease to dream in the moonlight of the past, and awake to the living present

A further and very important point is, that the recasting of the present academic course of education so as to include more science, and science properly taught, would tend to show the student his fitness for any particular profession much more clearly, and in this way it is extremely probable that very many who are not fitted by nature, inclination or education for the study of medicine would pursue other callings It is time that a halt was called to the absurd idea that, while every man may not be fitted for the study of a scientific profession, every one is adapted to the mould of the academic or classical college course Teachers of the experimental sciences declare that the students of the academic colleges form tread-mill habits which unfit them for the immediate study of science Prof Cooke, probably the best teacher of chemistry in this country, has written forcibly on this subject, and says "After that command of language which the necessities of civilized life imperatively require, there is no acquisition which we can give our children that will exert so important an influence on their material welfare as a knowledge of the laws of nature, under which they must live and to which they must conform," and he and all other teachers of science declare that this knowledge cannot be gained by recitations from books on "familiar science." There should be a course of preliminary study for the medical profession, and the medical colleges should require preliminary examinations, but the fact that a student may pass high in Greek, Latin, mathematics, logic, mental and moral philosophy, etc., does not form the least indication that he is fit to study medicine. Medicine is not a means of education, but an end requiring a certain line of education.

FORCIBLE INJECTIONS IN INTESTINAL OBSTRUCTION.

In the *American Journal of the Medical Sciences*, for January, 1886, DR. H. ILLOWAY, of Cincinnati, reports four cases of intestinal obstruction treated by the forcible injection of water, with three recoveries and one death. The injections were made with a powerful force pump, and repeated two, three or more times, as necessary. The post-mortem examination in the fatal case showed that a knuckle of the ileum had passed through a slit in the omentum and bent upon itself, and the intestinal structures about the incarcerated portion were somewhat softened, (death having taken place in a little more than a week after the symptoms set in.)

Dr. Illoway concludes from these cases that: 1. Enemata are superior to every other method of treatment. *a*. In the rapidity in which the cases are relieved. *b*. And in clearly indicating whether a surgical operation will be required. 2. They are entirely safe and free from all danger, and in no way prejudice the case should a surgical operation become necessary. It is due to Dr. Illoway to say that an operation was advised in the fatal case two days before death, and was refused. But for the length of time at which death ensued in this case, and the small amount of softening of the incarcerated portion of the intestine at this late date, we should be inclined to think that there may be an element of danger in forcible enemata in cases of some days' standing, namely, rupture of softened intestinal walls by the force of the injection and the pressure of the fluid. This fatal case must either be exceptional in regard to the degree of softening found, or we must think that the danger mentioned is comparatively slight until a longer time has elapsed. Of the two alternatives it must seem that the first should be held. It should be remembered, also, that the last injections were made on Tuesday, and that death took place on Friday, a sufficient time having elapsed for marked pathological alterations to take place. And it is entirely possible that had the forcible injections been made on Friday or the day before, the intestinal wall might have been ruptured.

However this may be, Dr. Illoway shows very conclusively that forcible injections are of great utility in promptly relieving some cases at least of one of the most unsatisfactory conditions with which the physician or surgeon has to deal. In the three favorably terminating cases the relief was permanent and almost immediate. In one of his cases an ordinary Davidson syringe had been tried without effect before the force-pump was used, from which it would seem that sufficient force cannot be obtained from an ordinary instrument. It is scarcely necessary to say that laparotomy should be performed if the force-pump proves ineffectual, with as little delay as possible. It will be remembered that in an editorial in THE JOURNAL of September 26, 1885, the treatment of intestinal obstruction was carefully discussed, and the following sentence quoted from the paper of Mr. Treves, read before the British Medical Association, at Cardiff: After twelve hours of treatment of acute intussusception with opium or belladonna and rest, it will be expedient to attempt reduction by means of insufflation or forcible enemata. This should be done in the first twenty-four hours, if possible, in order that laparotomy may be performed early.

COLLECTIVE INVESTIGATION OF DISEASE.

We have recently received the "Proposed Question paper No. 7," issued by the International Committee for Collective Investigation, which completes the series intended for collecting the facts concerning the geographical distribution and etiology of rickets, acute rheumatism, chorea, cancer, and urinary calculus. The memorandum and questions for the four first named of these diseases were very neatly arranged and printed for distribution in this country under the personal supervision of Dr. A. Jacobi, of New York, one of the American Members of the Committee, several months since, and it is earnestly desired that all who have received copies, or who may receive them soon, will carefully make the proper entry of all cases coming under their observation during the years 1885–6, and return them to either one of the American Members of the Committee early in January, 1887. The return at that time is necessary in order that the facts they contain may be properly collated for use in connection with those gathered in Europe, at the International Congress to be held in Washington in September of that year.

NINTH INTERNATIONAL MEDICAL CONGRESS —PROGRESS OF ORGANIZATION

Two or three of our exchanges still repeat the assertion that no material progress has yet been made in the Organization of the Congress This is far from being true On the contrary, the Preliminary Organization is at this time nearly complete *First*, notwithstanding all that has been said about *declinations*, a large number of those appointed and published by the Committee on Organization, as first constituted, still hold their places, and for every one who has declined two equally well qualified have cheerfully accepted positions *Second*, the only important vacancies now existing are in the office of President of the Sections of Physiology, Pathology, and Gynecology, the filling of which has been delayed by the Executive Committee for reasons we have stated in previous issues of this JOURNAL

Not only is the *personnel* of the Organization thus nearly complete, but the proper officers are actively engaged in arranging the work for each Section, and the Executive Committee will doubtless be ready to issue a supplementary circular containing a full programme, early in May next Already notices of contributions for several of the Sections have been received from prominent members of the profession in Great Britain, and indications favorable for a full European attendance are daily increasing

CHRONIC ULCERS —DR W P HOWE, of Charleston, Mo , writes to us saying, "that *lime* procured from barrels that have stood open for some time, sprinkled upon chronic ulcers will cure them when everything else, usually prescribed, fails Cleanse the ulcer with warm water and soap once every two days and fill the sore with lime no more bad odor, no more pain, and a remedy so cheap that it is within the reach of everyone

THE CHICAGO MEDICAL JOURNAL AND EXAMINER, for January, 1886, contains a connected and fair history of the origin and progress of the work for effecting the Preliminary Organization of the Ninth International Medical Congress If any desire such a connected history they can obtain it by applying to the Editor of that journal, 242 Wabash Avenue

THE DEATH OF DR J ORNE GREENE, of Lowell, Mass , is announced as having taken place on December 23 Dr Green was born in Malden, Mass , on May 14, 1799, and was therefore in his eighty-seventh year He was graduated from the Medical Department of Harvard in 1822

SOCIETY PROCEEDINGS

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirteenth Annual Meeting, held at Washington, D C, December 8, 9 and 10, 1885

(*Continued from page 24*)

THURSDAY, DECEMBER 10—THIRD DAY

EVENING SESSION

The Association was called to order at eight o'clock by the PRESIDENT, DR JAMES S REEVES

DR J M TONER, of Washington, stated that not having been present during the discussion of Dr Chancellor's paper, he wished to say in regard to the prevalence of pulmonary diseases in Washington, that it was due in a great measure to the large number of colored people in the District who, on account of their careless mode of living, without sufficient shelter and proper food, are predisposed to consumption, and further that many of the deaths occurring here do not belong really to our population, as they occur among people already fatally affected, and only stopping here on their way to a more southern and genial climate

A special committee on

DISINFECTION OF RAGS,

to consider the resolutions offered on that subject, was appointed as follows Drs J Howard Taylor, of Philadelphia, A N Bell, of New York, Henry B Baker, of Michigan, C W Chancellor, of Maryland, and H B Horebeck, of South Carolina

THE LOMB PRIZE ESSAYS

DR C W CHANCELLOR, Chairman of the Committee on the Lomb Prize Essays, reported that the Committee had carefully examined the thirty six essays on "Healthy Homes and Foods for the Working Classes," and had not found that any of them fulfilled the requirements In view of the fact that the essay bearing the motto "He who secures a healthy home and healthy food for himself and family does not live in vain" is one of great merit, the Committee had decided to award to it the second prize

The Secretary was then directed by the President to open the sealed envelope corresponding to the motto, and it was found that the author was Prof Victor C Vaughan, of Ann Arbor, Michigan

HON ERASTUS BROOKS, Chairman of the special Committee to award the prizes for the essays on

THE SANITARY CONDITIONS AND NECESSITIES OF SCHOOL HOUSES AND SCHOOL LIFE,

read the report of the Committee The Committee appointed by the American Public Health Association on "The Sanitary Conditions and Necessities of School Houses and School Life," and to whom the Secretary has forwarded twenty papers, covering from twenty-two to one hundred and sixty-five pages, report

1 That they have given to the papers the attention due to the importance of the subjects discussed All of them present subjects belonging to the proper

care and character of common and private schools—to building, their management indoors and out of doors, and especially to school hygiene Everything relating to physical education and general health is presented, and under these and other subdivisions of subjects all that relate to scholars at school and scholars at their homes, to every form of possible school disease, to proper hours or times of study, to school age, to light, and diet and clothing, to heat and cold, sleep and needed recreation, to proper kinds and times and places of exercise, of general eye sight and all diseases of the eyes, to baths, bathing, and all distempers and maladies to which children at school are exposed, to school architecture, accompanied with valuable illustrations of the best styles of building, to school grounds as to places, grading, and finish with reference to the plans known as the system or plans of Mr T M Clark, of Boston, the Sargent system of Cambridge the Briggs plans of Connecticut, the Swedish system of Lying, and almost every system founded upon knowledge of the human body Bodily punishment is opposed in all the papers, except in very rare or extreme cases, and one reason given is that lethargy, idleness and disobedience may come, and do often come, from evils in the schools where severe rules are the near or remote causes of the evils complained of So likewise, school competitions are censured as exciting the nervous system too much, and often arousing jealousies and ambitions which result in no practical good to those who are pitted against each other School exhibitions in the heat of summer are also condemned Where competitions and exhibitions are desirable, the exhibitions and recitations should not be in public No one school, it is held, should exceed 600 pupils, and where, as in the schools of New York City, out of 2,300 very young pupils examined only 122 had at best perfect eyesight, it becomes too apparent that the crowded condition of schools is largely responsible for the increasing defective eye sight in young persons All the more is this apparent and suggestive when it is known that myopia becomes a progressive disease Where careful examinations have been made, it is shown that, starting from nothing, from 60 to 70 per cent of the scholars have in one form or another, impaired eye sight, and that from 10 to 25 and even 30 per cent in some schools have impaired hearing

2 In reading these several essays we are impressed with the fact that those who most need the information given in them are from prejudices, habits of life, ignorance and other reasons, the least likely to be benefited by the facts and statements they contain But this truth only shows the constant necessity of this form of education, and the duty of those who are blessed with means, experience and knowledge of improving every opportunity to impart to others, and in every practical manner, the result of their own study and investigation In this spirit Mr Henry Lomb, of Rochester, in the spirit of the largest generosity, has made the American Public Health Association the vehicle or instrument of his several benefactions for the health, comfort and instruction of the people of the State and Nation The act is worthy of all honor, and the example deserves the thanks of the people and the congratulations of wise and good citizens of the whole country

3 If children are forced to go to school by the State, the State owes them instruction in what belongs to the mind, and if this is admitted, physiology and anatomy ought to be taught in all schools, as the recent statute requires in the State of New York In a very important sense the body and mind are one, and especially are they a unit in about all that relates to health Physical and mental education should receive equal attention

4 The limited time due to any one study, and the proper directions of all studies, according to age and bodily or mental conditions, present subjects apart from overwork in the school room The suspension or continuance of studies in the interest of education also presents this subject wholly apart from what is called too much study or overwork in the school room

5 Among the specialties named and urged in some of these papers are the appointment of regular medical examinations both of teachers and scholars, the examiners to be qualified physicians or inspectors, and these persons to know that the teachers have in all respects intellectual fitness for their tasks as teachers Such appointments would direct and control all that belongs to school hygiene, all that belongs to vision, the source of so many evils to pupils under the present neglected systems, of what belongs to light, air, bodily positions, time and place of lessons, and of what is due from teachers in regard to physical and scientific development both of mind and body These medical examinations, it is believed, would result in the double good of saving life and promoting health, of separating those afflicted with contagious and other diseases from those who are free from them It is urged that for these reasons there should be some annex for the feeble in body and mind If the State is ready to enforce the separation of dumb animals—the healthy from the diseased—it is urged that the State should be at least quite as ready to separate school children whose presence one with another endangers the health of the pupil, of the family, and of the whole community If, in a sentence, a quarantine is required for the cattle and hogs of the country, a like quarantine should be provided for the little ones who already are the children of the State, and if alive hereafter to be the fathers and mothers of the country

6 It is also urged that teachers should be licensed to teach and their qualities proved before they enter upon their work At present politics, prejudice, sects in religion and prejudices in party, with ignorant men to select and decide in the choice of teachers, too often and most often are the motives and purposes of the successful choice If anywhere in the public service an intelligent and honest civil service is needed it is in the selection of teachers in our common schools If discretion, wisdom and righteousness are required upon the Bench, at the bar, in the general business of the State for the people at large, or in the teachers from desks dedicated to God, these qualities are surely none the less re-

quired in the great work of teaching the millions of children in a country whose population ere long, judging from the past and present, will number nearly one hundred millions of people

7 One of the papers, chiefly for reasons of freedom in fitting places of recreation, favors the co education of the sexes, between the ages of beginning study (which varies from 5 to 8 years) and the age of 14, excepting for children under 5 and in attendance upon kindergarten schools, where the hands and the eyes are made useful almost by observation alone

The study of music, especially where the fingers are used, is urged for strengthening the hands, as the voice may be used for strengthening the lungs As a system, also, the Swedish, which is denominated educational, æsthetic, military and medical, is the oldest, and with many the most approved, for the reason that under one of these heads is taught the best kind of free exercise, under the second is taught what belongs to the expression of ideas and sentiments by means of positions and movements and what may be called grace of manner The use of the sword, foil and bayonet belong to the third classification, and the law of Congress of 1862 requires instruction in all these weapons, and in all that belongs to early and practical lessons in military service Under the fourth, or medical head, instruction is enforced in what belongs to the treatment and cure of chronic diseases and deformities, through the use or agency of free movements, with or without assistance, resistance by special apparatus, or by manipulation These four exercises are intended for the harmonious development of the body, and secure the end desired While this system is generally approved, it is proper to say that it is also criticised and opposed as wanting in spirit and energy from the absence of apparatus and the absence of motive to complete a definite object

8 As a substitute for the long time devoted to study in school, it is suggested that the full school hours be divided between books and work, and some kind of useful mechanical work, if possible In the general order of proper school education we suggest

First, A sanitary education for the body and the mind

Secondly, Mechanical instruction in the interest both of mind and body

Thirdly, And in this order, appropriate school studies from books

While this is reversing the common methods of school education the beginning, at least, here suggested, is in the right direction, and should be insisted upon by the State and by all in authority having charge of our public school system Your Committee, in view of the important subjects presented to them, venture to suggest and to recommend these conclusions

First In regard to teachers, and in the interest of the health of children entrusted to their care, that other knowledge than teaching the ordinary lessons of the school room is desirable

Secondly That the highest object of life, next to moral conduct, is the health of the old and the young, and that the chances of health in middle life and old age are almost impossible where a wise sanitary foundation has not been established in the period of time usually devoted to school life

Thirdly That the examination of the large number of papers submitted to the Committee proves the necessity of a much greater interest in the sanitary condition of school houses, and of a much larger common interest in school life In the use of the eyes from various causes, fully enumerated in papers before the Committee, it is shown that the disease known as myopia has increased from nothing to 50, 60 and 70 per cent, and in parts of Germany to 79 per cent That schools very often are but so many factors of near sightedness, that parents and their homes share in the responsibility and cause of this great grievance in common with teachers and school houses This is also true, though not to the same extent, in the bad use of the ears, in defective light, in foul air and bad ventilation These great defects in school rooms and homes, in teachers and pupils, are all the time progressive in parents, homes, teachers, and pupils, from class to class, and from year to year

Fourthly That in not knowing what was necessary to secure the health of the present generation, our honored ancestors, in a large sense, became responsible for the ignorance, deficiencies and diseases of the present, and the present generation will in turn, by persistent neglect and ignorance, become responsible for like consequences in the future We all well enough know and understand what inheritance means when it results in personal good fortune or family estates, and we ought to know what inheritance means when the effect is to impart vice, disease and death upon those who are to succeed us Fortunately for the State and country, the American Public Health Association is established to teach, among other lessons, the necessity and value of hygiene for the young as well as the old, especially in all school life, as well as among adults in the homes and workshops of the country

The Committee did not consider any one of the papers presented as worthy of the first prize The second was awarded to Dr F Lincoln, of Boston

(*To be concluded*)

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, December 3d, 1885

THE PRESIDENT, B F BAER, M D, IN THE CHAIR

DR ELLIOTT RICHARDSON read a paper on

SOME CAUSES OF TARDY FIRST STAGES OF LABOR, AND THEIR TREATMENT

(See p 32)

DR PARVIN remarked that the subject of Dr Richardson's paper was one of great practical importance, and his presentation of it has been very interesting Coming to its ultimate analysis, a case of labor, tedious in either the first or in the second stage shows a want of proper relation between power and resistance, the former for an unusually long time is unable to overcome the latter Manifestly, if this be so, we have naturally suggested to us two plans of treatment either increase the power or lessen the resistance These principles are plain, but the selection and the application often present serious difficulties Severe suffering in the first stage of labor certainly should be relieved, for this suffering exhausts, and it does not follow that the power of a pain is to be measured by the intensity of suffering it produces, and therefore "painful" pains are an undoubted evil As to the means for their relief when they are associated, as they usually are, with very slow dilatation, many would prefer chloral injected into the rectum to morphia internally, or an æsthetic inhalation

In regard to the process of dilatation of the os, it is possible Dr Richardson has attached too much importance to the bag of waters as a dilating means, that is the mere passive process, but there is an active process—that by which the circular fibres of the uterus are, by the action of the longitudinal fibres, retracted over the bag of waters, or the presenting part, if the former be ruptured, it is not so much descent of the presenting part which occurs as it is the ascent of the expanded cervix, for in primiparæ, at least, the head is usually, at the beginning of labor, in the pelvic cavity, and it can go no farther until the dilated os has passed more or less completely above it It may be that resistance being lessened by chloral, or by opium, the power is sufficient to overcome it, but if it be not, probably the continuous current of electricity will be the most efficient means to increase the uterine force In this connection I may refer to the statements of Bayer, in his recent elaborate monograph entitled *Morphologie der Geburmutter* In many cases of labor where delay occurs in the first stage, it is not the os uteri that is at fault, the obstacle is higher up, and according to Bayer, the anatomical condition of this "*Stricturirung*" is the deficient unfolding of the cervix In such condition there may be a spastic ring like stricture or a spastic partial stricture The first form is especially liable to occur in a narrow pelvis Bayer recommends warm fomentations, warm vaginal irrigation, a whole bath, eventually narcotics, especially opium by rectal injection, but he strongly insists upon the continuous current as the true natural method of treatment, on the one hand relieving cramp, and on the other exciting labor, activity thus removing the primary failure, the deficient unfolding of the cervix

One word as to the occurrence of malarial poisoning in the puerperal woman I think it comparatively very rare Certainly this is the conclusion which I must draw from my own experience in private and in hospital practice In two terms of service at the Philadelphia Hospital I have seen probably forty cases of puerperal septicæmia, and only one case of malarial fever When one sees a febrile attack in a woman after labor, he is disposed to take the most favorable view of the case and may attribute, at first at least, the disease to malaria when really it is caused by septicæmia, losing precious time, and may be led to give a favorable when a doubtful prognosis should be indicated

Dr W W Jaggard, of Chicago, upon invitation from the Chair, remarked that morphia hypodermically had been extensively tried in the first stage of labor at Vienna and Paris, and had been discarded, in the former city about six years ago, and in the latter more recently It had been found to affect the fœtus unfavorably One fourth of a grain administered every four hours for some time would be attended with grave elements of prognosis The possibility of a live fœtus remaining in the uterus forty five days after the escape of the amniotic fluid he considered more than doubtful Cysts sometimes form between the amnion and chorion, and the bursting of one of these may give rise to the idea of the escape of the amniotic fluid Hydrorrhœa gravidarum, a condition dependant on a diseased condition of the decidua, is a more frequent phenomena, and will explain many of the cases of supposed rupture of the amniotic sac

Dr W T Taylor remarked that the causes of delay in the first stage of labor were numerous For the relaxation of rigid os he would prefer hydrate of chloral twenty grains, one eighth of a grain of sulphate of morphia every two hours has a soothing and beneficial effect, giving rest and sleep between the pains When the edge of the cervix is thin and wiry, the morphia is especially called for He has experienced delay from dropsy of the amnion After a delay of six or eight hours he has ruptured the membranes and after the escape of an enormous quantity of fluid, rapid and effectual contractions supervened Another cause of delay is posterior position of the occiput, if a change of position can be effected labor will progress more rapidly He has observed premature escape of the liquor amnii from ten days to two weeks before labor, and yet everything went on normally He has met with one case of malarial poisoning In the eighth month intense pains were experienced, but there was no effect on the os He gave five grains of quinine and two grains of potassium bromide, and in a few hours the pain was relieved

Dr Longaker stated that according to his experience morphia should be used gradually In some cases it has caused still births In a recent case the first stage of labor had lasted twenty-four hours and the os was but one inch in diameter, four doses of sulphate of morphine, one fourth of a grain each, were, by mistake of the nurse, given at intervals of fifteen minutes dilatation and descent of the child quickly followed As Dr Parvin has stated, the early stage of labor consists mainly of retraction of the cervix, and early rupture of the membranes as a trouble is overrated Undeveloped pelves of generally small diameter cause less delay in first labor than in later ones, because in the earlier labors the abdominal muscles are strong to assist the uterine contractions, in later labors, besides having less contractile powers, their laxity allows the body of the child to fall forward, and the vertex presents less favorably at the superior strait

Dr Trautmann said that in one case under his care recently he found a well dilated os uteri and a free escape of waters, the pains ceased, ergot was given without any effect, and as the forceps were strenuously objected to he was obliged to do nothing. After an interval of four weeks labor came on naturally and a living child was delivered. The unaccountable facts in this case are the widely dilated os, the escape of the waters and a living child four weeks later.

DR. W. S. STEWART said that sodium bromide is good to prevent premature labor, five drachms may be divided into ten doses and one given every three hours. He has observed in one patient an apparent rupture of the membranes at five months, the fluid coming away with a constant drip, later the flow was greatest at night, this condition lasted for six weeks, when it terminated in premature labor, the fœtus was living. The fluid which came away was examined and seemed to be amniotic. He also has observed retardation of labor from falling forward of the fœtus in relaxed abdomen, when such a patient is placed on her back labor goes on rapidly.

DR. CHAS. M. WILSON remarked that hydrorrhœa gravidarum is more frequent than is supposed, and is mistaken for premature discharge of the amniotic fluid. Rigidity of the os uteri is most quickly relieved by inhalations of chloroform. He has found its action more satisfactory than that of chloral and sodium bromide or ether, and safer than morphia. Postural treatment of early stages of labor is of the greatest importance, he would place the patient on the floor on her knees or haunches holding by the back of a chair or post is often useful, as it assists in fixing the respiratory muscles. He has not had good results from the local use of belladonna.

DR. KEATING spoke of some experiments he had been making. The patient was first to practice Dr. Bonwill's method of inducing partial anæsthesia by rapid long breathing for a time, and then to hold the breath as long as possible. This method was found to bring on rapid and efficient pains in the multiparæ with pendulous abdomen.

DR. BAER remarked that take it all in all, morphia hypodermically is the most valuable remedy we possess for the relief of pain and rigidity of the cervix during the first stage of labor. Of course it must be used within proper limits.

DR. RICHARDSON, in closing the discussion, said that his paper was not intended to be comprehensive. His use of morphia extended only to doses of one-sixth of a grain every four hours, by the mouth, and not hypodermically. In the patient whose history he had given, intermittent fever was developed later on, and he has not the slightest doubt of malarial poisoning being the cause of the untoward symptoms during and after labor, there was no fever, no rise of temperature, and therefore septicæmia is excluded. There can be no question as to the retraction of the cervix when the head is already in the pelvis, but when the head fits tightly into the superior strait and the cervix is jammed by it, the pressure upon the upper sac is greater than upon the lower, cut off from it by the head. Chloroform is more efficient than any other agent he had used, but it was not always to be preferred.

(*To be concluded.*)

CHICAGO GYNAECOLOGICAL SOCIETY

Stated Meeting, Friday Evening, Nov. 27, 1885.

THE PRESIDENT, DANIEL T. NELSON, M.D.,
IN THE CHAIR.

DR. JOHN BARTLETT read a paper entitled

REMARKS ON THE TOXIC PROPERTIES OF SASSAFRAS.

Sassafras was discovered in Florida by the Spaniards and named by the French in 1562. It was used by them in association with other native herbs as a remedy for malarial diseases. Though occasionally prescribed in combination in rheumatism and syphilis, and regarded as possessing diuretic, diaphoretic and tonic properties, it has fallen into disuse. So that by referring to such books as were within my reach, namely, Motherby, 1785, Parr, 1809, Eberle, Trousseau, Mitchell, Warring, Stillé, Ringer, Bartholow, Phillips, Wood, Fluckeger, Farquharson, Brunton, Wormly and Blyth, and the U. S. Dispensatory, National Dispensatory, Christison's and King's Dispensatories, I can find no mention of the possession by sassafras of any decided therapeutical or noxious power.

More than twenty years ago Dr. Thomas, of Tennessee, stated that sassafras was an antidote to henbane and tobacco, and later, in 1870, Dr. Lyle, of Indiana, declared that he had used *the oil of sassafras* in a case of stramonium poisoning with the happiest results. Dr. Lyle affirmed that sassafras had power to destroy all insect life, and was an effectual antidote to the venom of the copperhead snake. In 1883 we find that Dr. Hinton claimed that sassafras tea was almost a specific for the rash produced by poison oak. Recently paragraphs have appeared in the medical journals, in which it is stated that sassafras is not the innocent agent that it has been supposed to be, but that in reality it has violent toxic properties. This statement is made upon the authority of Dr. Charles I. Hill, from whose paper read before the 86th session of the Medical and Chirurgical Faculty of the State of Maryland, in April, 1884, the following report is extracted.

"A case of poisoning by the oil of sassafras, that once came within my knowledge, proved that it possesses far more active properties than is generally supposed, and I have been able to demonstrate by experiment on the lower animals that, instead of being a harmless, inert drug, it is a strong nervous sedative, anodyne and soporific, and in over doses, a dangerous narcotic poison. A policeman, attracted by the sound of a falling window and other suspicious noises proceeding from a gentleman's office, entered the room to ascertain the cause. He found no one present but a boy, who was lying unconscious on the floor. He took him at once to the station house, where I saw him shortly afterward. The officers had already diagnosed his case as one of opium-poisoning, and were vigorously striving to keep him awake by walking, flogging and such other means as are usually resorted to in these emergencies. His stupor was profound and he no longer made an attempt to walk, but was literally dragged about in their efforts to revive him He spoke occasionally, but only to beg them to allow him to sleep He was in a condition of great relaxation, skin covered with a profuse perspiration, countenance pallid, pulse rapid, but weak and thready His pupils were *normal*, and there was a strong odor of sassafras in his breath As quickly as possible an emetic was administered, which produced a copious emesis, redolent with the odor of sassafras, with drops of the undissolved oil floating in the liquid This was followed by free draughts of warm water, until only a faint odor of sassafras was discoverable The vomiting relieved him and he was soon restored to consciousness He felt no discomfort except a sense of weakness and exhaustion, and was soon able to give the following account of himself His employer having gone home, he was preparing to close up the office, when he espied a bottle of the oil of sassafras which had been left on the desk Remembering that sassafras had been recommended for the removal of an eruption that disfigured his face, he thought this a good opportunity for giving it a trial, and turning up the bottle—to use his own language—he took two large swallows of its contents In a few minutes he began to feel very *stiff*, as he expressed it, but proceeded to close up the shutters preparatory to leaving for home He raised the window for this purpose, but had not strength to hold it in this position, and it dropped from his grasp, and at the same time he fell to the floor unconscious This suggestive case led me to make numerous experiments on the lower animals with very interesting results Ten drops of the oil were injected hypodermically under the skin of a mouse The animal quickly succumbed and died convulsed By repeated experiments I was able so to regulate the dose as to get the characteristic effects of the drug without causing the speedy death of the mouse A glass rod was dipped into the oil and held in front of the mouse, and he seized it with his mouth This was repeated at intervals of a few minutes, until a sufficient quantity was taken to produce the desired effect The first symptoms observed when a small quantity was thus taken, was a slight convulsive movement, which was repeated at intervals of a few seconds, and agitated the animal's body very much like a severe hiccough This gradually increased in severity, the movements became more unsteady, the body more arched, and the limbs so stiff that the mouse stood on tiptoe It was noted that the one idea of escaping from the trap still predominated over all else, as he continued to climb up on the bars of the cage, only to fall on his side or back at each convulsion, until no longer able to rise

I have repeated these experiments many times with great uniformity of result Sometimes they would dance about for half an hour, with a peculiar convulsive movement that would jerk the head and front feet from the table Again they would fall on their side with each convulsion and regain their feet immediately, only to repeat the same movement With cats and dogs the result was somewhat different A drachm under the skin of a cat caused such profound insensibility that she was supposed to be dead, and thrown away, but it seems that only one of the reputed nine lives of the animal had been reached, as the next day she turned up none the worse for the experiment A full grown dog was paralyzed in his hind legs by a similar dose hypodermically over the loins, but it recovered Many other experiments might be adduced, but I will not trespass on your time There is one other property possessed by this drug that is worthy of mention—it is a germicide and anti ferment of no mean quality In some clumsy experiments made by myself I have estimated its potency in this field as about one half the strength of carbolic acid It has long been used as a domestic remedy for the destruction of lice and other vermin

For some years past I have had an intention of bringing before the profession reasons, rather feeble it must be admitted, for the supposition that the medicine under consideration has marked potency in a direction, so far as I know, not suspected by medical men Up to this time the declaration on the part of standard writers that sassafras is a remedy of questionable power, and the fact that it is hawked about the streets and used freely as a tea all over the country, have caused me to refrain from bringing before a scientific body my limited experience presently to be detailed But the recent declaration that this drug possesses toxic properties may justify me in making the following statement Years ago I was called to a woman among the poorer classes, of good intelligence and education, who was having a miscarriage Upon my inquiring as to the cause of the mishap, with a prefatory reference to her poverty and already large family, she stated that she had induced the abortion herself—that she had done so on previous occasions She had employed, she said, "what other women used," sassafras tea She was surprised that I did not know of the property of sassafras as an oxytoxic She spoke as if all her friends knew how to use it as an ecbolic, and she evidently looked upon it as a specific Tea, she said, made from four or five pieces of the root, as large as the thumb and twice as long, would produce abortive effect

A year or two later I was called to a woman two months pregnant For several days she had had symptoms of miscarriage of so pronounced a character that arrest of the process was doubtful I found the patient very anxious to have a child, she disclaimed the intention of inducing abortion, and to all my inquiries as to a possible cause of the hæmorrhage, she gave answers which left me no further question except this "Have you been drinking sassafras tea?" Surprised, she replied that for a week past she had used it at breakfast and supper The proper remedies for her condition were prescribed, the possibly offending tea left off, and in twenty four hours all was quiet *in utero*

Farther than this my experience with sassafras as a possible abortifacient does not extend, possibly some one present can supplement my remarks with knowledge or experience of his own A study of the toxic effects of sassafras as reported by Dr Hill, and here suggested, would seem to show a triple resemblance to three familiar articles, opium, strychnine and ergot. In its action as a narcotic and sudorific it resembles opium. In its property of inducing tetanic and clonic spasms, followed by paralysis, it is similar to strychnine. In its power hinted at of exciting the uterus, it may be linked to ergot. It may be of interest here to call attention to the fact that the first reference to the use of ergot as an ecbolic was made by Stearns in 1807, whereas it had been used by midwives certainly as early as 1688, and probably very much earlier.

Dr. James H. Etheridge, referred to the action of the oil of sassafras on the motor centres in the spinal cord, supplying the uterus.

Dr. Edward Warren Sawyer said in New England sassafras was a popular emmenagogue. Mothers were in the habit of giving decoctions of sassafras and tansy to their daughters in case of delayed or suppressed menstruation. Many of the essential oils produced the effects ascribed to sassafras by Dr. Bartlett. In the South, oil of sassafras was a popular remedy for uterine disease.

The President inquired as to the chemical constitution of the volatile oils?

Dr. H. P. Merriman replied that many of the volatile oils were identical in chemical relations, but differed in physical properties. Such oils were *isomerides*. The essential oil of lemons, of bergamot, neroli, lavender, pepper, camomile, caraway, clover, etc., are isomerides of the oil of turpentine.

Oil of sassafras was an isomeride, whether or no of the turpentine group, he could not say. Oil of turpentine was a hydrocarbon, possessing the formula $C_{10}H_{16}$.

Dr. H. T. Byford was of the opinion that the oil of sassafras exerted its influence locally upon the alimentary canal and pelvic viscera, through which it was excreted, rather than upon the uterine nervous centres, as in the case of ergot. This would account for its popularity as an emmenagogue, mentioned by Dr. Sawyer. He had recently given one drop, combined with one-half grain of piperin, every three hours, for two weeks, in case of typhoid diarrhœa. Slight strangury, disappearing with the discontinuance of the drugs, was produced.

(*To be concluded.*)

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT.)

Mortality from Zymotic Diseases in England—Overcrowding among Workmen—Nitrite of Amyl in Opium Poisoning—An Attack on Pasteur—A New Lead Battery.

During the past ten years in England, there appears, from the decennial report just issued by Dr. William Ogle, of the statistical department of the General Registry Office, to have been a most satisfactory falling off of the mortality due to the various zymotic diseases, with the exception that whooping-cough has remained stationary, and that from small-pox a large increase of from 163 per million living to 236 per million. This increase is due to the very serious outbreak which marked the two first years of the decennium, 1871 and 1872, and which led to the appointment of compulsory vaccination officers by boards of guardians, and consequently to a more stringent enforcement of infant vaccination. If, however, the statistics of small-pox are given by what Dr. Ogle calls natural periods, that is, by periods which coincide with successive improvements in the enforcement of the vaccination acts, it becomes manifest that there has been a gradual and notable decline in the mortality from the disease. It may be further shown that this decline is due to diminished mortality amongst children of tender age, while the mortality at later periods of life has actually increased, and has increased in proportion to the age attained. The explanation seems to be that when regarded by the light of long experience, vaccination confers an immunity from small-pox which is as real as, but less permanent than, that conferred by small-pox itself, so that the protective influence of the former requires to be renewed from time to time. This precisely coincides with the results which have been recently set forth by the German Commission appointed to inquire into the subject.

Taking the other principal zymotic diseases, it pears that the annual deaths per million living, from scarlet fever, have fallen from 972 to 716, those from fever, including typhus, enteric and ill defined forms of continued fever, from 885 to 484, those from diarrhœa, from 1076 to 935, those from phthisis, from 2475 to 2116, and those from diphtheria, from 185 to 121. Under the two last headings, however, there is some uncertainty as to how far the improvement may be only apparent and due to more exact statement of the causes of death upon the medical certificates. Diphtheria is probably less liable than formerly to be confounded with other forms of fatal croupous affections, and phthisis is less liable to be confounded with other forms of diseases of the respiratory organs, under which latter heading the fatality has increased. The report contains much valuable information with regard to the mortality produced by many other diseases. It may be mentioned that the deaths of women in childbirth have remained practically stationary for the last thirty years, and that they amount to something less than five for every thousand children born living.

The total death rate during the ten years, 1871 to 1880, is 21.27 per thousand, varying in different localities from 14.13 and 33.57 per thousand. Among the 647 districts into which England and Wales are divided, there were eight in which the mean annual rate was under 15 per 1000, 31 more in which it was under 16, and again, 62 others in which it did not exceed 17. These 101 districts are described as the "selected healthy districts," and form a useful standard for comparison. In 326 other districts, the mean annual death rate was between 17 and 20, in 190 it was from 20 to 25, in 23 from 25 to 30, and in the remaining two it exceeded this high figure. Dr. Ogle attributed these differences partly to difference in the quality of the sanitary administration, partly to the different density of population, and partly to unwholesome occupations

Mr Middlewick, in a paper read before the Association of Public Sanitary Inspectors, took up among other points, the subject of overcrowding as the result of a necessity for the workman to live near his work and urged the remedy which has been so much discussed, of the extension of living ground out of London by the installation of a regular system of workmen's trains Previous evidence in regard to this point shows that it is very doubtful whether this system would be accepted by the mass of artisans, or whether it could be made to pay Mr Middlewick also attacked the "model dwelling" system, on the ground that the rents were too high in such buildings and that there was very little recreation ground in connection with them in comparison with the number of children who lived in them The latter statement is certainly true, but it is connected with the former inextricably The aim of most people who promote model dwellings is to make them remunerative at as low rents as possible If more ground is taken, rents would be proportionately higher, unless the buildings are to become a mere charity establishment for finding people homes at rents convenient to their means

The following case, in which nitrite of amyl was used as an antidote to opium, will doubtless be considered sufficiently important to lead others to try the same treatment in desperate cases of opium poisoning The case recorded is of a person who took two ounces of laudanum, and showed every symptom of opium poisoning—coma, small pulse, feeble and infrequent respiration (six to the minute), coldness and cyanosis Belladonna proved useless, while inhalation of nitrite of amyl immediately improved and ultimately restored the patient

M Henry Rochefort is never happy for a long time, if some one, or some thing, is not attacked in his organ This paper has made itself remarkable by the acerbity with which it has attacked M Pasteur, whose equanimity, however, is not disturbed A week or so ago it printed a sensational paragraph concerning a tragic incident which it affirmed had just occurred in Paris. A child six years of age who had been bitten by a mad dog was placed by her parents under M Pasteur's care, and, as the paper asserted, had lost her life in consequence of his treatment As a matter of course, the absolute correctness of the story was vouched for, defying M Pasteur to contradict it It turns out, however, that it omitted to state the real truth, which very materially alters the circumstances of the case related The little girl placed under M Pasteur's care met with the accident which proved fatal six weeks before he was consulted The dreaded malady—hydrophobia—had consequently time to develop itself, and the case, evidently, cannot be accepted as furnishing a proof against the value of the distinguished savant's theories

A new medical battery has come out, in which the authors use lead in place of zinc, as the positive element, which is easily reducible from most of its compounds As the negative element, they employ a conductor, preferably of lead or carbon, coated or kept in contact with a layer of peroxide of lead

The honor of knighthood has been conferred on Dr James Sawyer, the well known physician of Birmingham

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Indications for Laparotomy in Penetrating Stab and Shot Wounds of the Abdomen—Vaginal and Vulvar Enterocele

The last meeting of the Surgical Section of the Academy of Medicine, held December 14, was one of unusual interest The subject for discussion was, *The Indications for Laparotomy in Penetrating Stab and Shot Wounds of the Abdomen*, and several prominent surgeons and gynecologists took part in the debate It was opened by Dr Joseph D Bryant, who went over the ground more carefully and systematically than any of the other speakers Taking for his text the dictum 'Laparotomy should be performed in all cases and immediately after the accident," he said that he who unconditionally asserts that any operation or method of procedure should be performed in all cases, even though it be a measure accepted by the profession generally, takes a position which requires, in justice to the profession and the patient, that all operators should be competent and well equipped for its performance Especially was conservatism necessary in the advocacy of an operation the propriety of which, as yet, is spoken of by many with doubt commingled with dread Few indeed were the hospitals in the city of New York which could "immediately after the accident" offer the recognized facilities necessary to dispatch and cleanliness in operating, not to mention other circumstances bearing on the success of the procedure How much less properly prepared for the performance of laparotomy would the unfortunate patient find the general mass of the profession?

He thought it well to divide the dictum referred to into three interrogatories, and the first was, *Should laparotomy be performed in any case?* It could not be denied that laparotomy in connection with various abdominal growths was a fully established operation, and there was no proof, so far as he knew, that the peritoneum of the male was not as tolerant of manipulations as that of the female Again, the success of Billroth and many others in operations upon the stomach pylorus, kidneys, etc , fully showed that intolerance of the peritoneum could not be considered as a rational objection to laparotomy, while these operations showed also that neither could the length of time required nor the great extent of raw surfaces resulting in many instances be urged as objections

Among the practical elements which at the present enter into a case of laparotomy for penetrating wounds, but which do not exist, or at all events exert an equal force, in laparotomy for other common causes, he mentioned the following (1) *A doubt* *whether the abdominal viscera were injured.* Although this doubt, at best, could exert but little influence, it could at once be set at rest by an exploratory incision. (2) *Existing shock.* He believed it to be an established fact that when severe shock follows immediately after the injury it is due, in the great majority of instances, to loss of blood, and if this were the case, the indication was to check the hæmorrhage at once. An exploratory incision would decide this question also. (3) *Unfavorable surroundings of the patient.* It was impossible to avoid such circumstances entirely, but their dangers could be greatly lessened by caution in moving the patient, by taking at once to a suitable hospital, instead of his own home, and by increased familiarity on the part of the profession with all the details pertaining to the proper performance of laparotomy. (4) *Unskilled operators.* This element could be altogether overcome if the members of the profession would only devote a reasonable amount of attention to this important subject. (5) *Greater exposure of the abdominal cavity and its contents.* (6) *Existence of hæmorrhage.* The vessels of the omentum and of the intestines, especially the former, bled with unusual pertinacity, and the suspicion of the existence of much intra-abdominal hæmorrhage was enough to indicate the making at least of an exploratory incision. (7) *Extravasation of intestinal contents.* This was the strongest of all the indications for laparotomy, which offered, indeed, the only chance of recovery, and here again, when such a condition was simply suspected, the exploratory incision was called for to determine the question. (8) *The greater difficulty of cleansing the abdominal cavity.* If blood and intestinal contents had been generally diffused, the cleansing of the abdominal cavity was more tedious and difficult, and also of greater importance, than in laparotomy for other causes, but the thorough performance of this duty, at least so far as the intestinal contents were concerned, appeared to be the only means of saving the patient's life. As to blood, no one could tell the amount that might remain, and yet recovery take place. In Dr. Bryant's opinion, laparotomy was a justifiable operation in penetrating abdominal wounds, but it was not to be attempted, even in so called favorable cases, unless the operator could avail himself of many of the recognized means of procedure and was sufficiently familiar with its steps to do the work with accuracy and dispatch.

Leaving the second interrogatory, *Should laparotomy be performed in all cases?* to be discussed by others, he passed on to the third, *When contemplated, should it be done immediately after the accident?* Assuming all things to be equal, he thought that it should be done at once, or at least as soon as the necessary preparations could be made. In most cases there should first be an exploratory incision, and then this should be followed, if the condition of affairs warranted it, by the actual laparotomy. In the former the incision was made in the median line, so situated and of sufficient length to expose to view the probable seat of the internal injury. The surgeon could then, in the great majority of instances, determine if penetration of a viscus had taken place, and if hæmorrhage or intestinal extravasation existed. If the patient were in danger from immediate hæmorrhage, the blood could be seen in the abdominal cavity through the opening. In conclusion, Dr. Bryant asked, *Does the exploratory incision expose the patient to unusual dangers?* The large number of successful laparotomies both in this country and abroad seemed to him to answer this question in the negative, and if this were true, he said, all that was possible was gained, while but little could be lost from the exploratory incision.

Dr. J. Williston Wright said he was not prepared to take the ground that all cases of penetrating wounds of the abdomen were to be treated by laparotomy. As regards gunshot wounds, it would be found that the large or small size of the missile, as well as the velocity of the latter, made a great difference in the severity of the injury. Dr. Wright facetiously expressed his contempt for the ordinary 22 calibre revolver bullet by saying, that if any one were to shoot him with one of these balls he should feel it his duty to go across the street and kick the individual firing the shot. As a rule, such a bullet lodged in the abdominal walls, but even if it did penetrate the cavity and pass through a knuckle of intestine, the opening made by it was so small that an eversion of the mucous membrane was caused, which would be sufficient to prevent the extravasation of fecal matter, while the hæmorrhage would be but trifling. But if, on the other hand, he were called to a case in which the injury had been inflicted by what is known as an "express charge"—a 40 calibre bullet weighing 270 grains, with 110 grains of powder behind it—he would expect to find abundant indications for the performance of laparotomy, and even in the absence of symptoms, he would consider the case one for immediate operation, because he would feel very sure that if such a missile got into the abdominal cavity at all, it would cut and tear everything that came in its way.

In stab wounds he said he would not perform laparotomy in many cases, even if he knew that the wound were a penetrating wound, or even if the omentum were protruding. In this connection he mentioned the case of an intoxicated sailor who stabbed himself in the abdomen, and when a portion of the omentum protruded through the wound, caught hold of it in his drunken folly and dragged it still further out. Yet the man recovered perfectly, and that without being laid up for an hour. He also mentioned a somewhat similar case at Bellevue, that of Carpenter the murderer, who stabbed himself in the abdomen.

Dr. R. F. Weir said that in penetrating wounds, unless there were symptoms indicating injury of the intestines or abdominal viscera, he did not think it was advisable to interfere. With gunshot wounds, however, the case was different, and he did not hesitate to acknowledge that he had more respect for the small bullet than Dr. Wright. As a rule, one of the indications was to explore the wound under any circumstances, and he thought that statistics clearly proved that every gunshot wound of the abdomen at short range should be carefully examined in order to see whether it penetrated the cavity. If there was shock which did not proceed from hæmorrhage, it was best to defer laparotomy until this had passed, but he agreed with Dr Bryant that it was best to make a small exploratory incision in every case where it was impossible to decide whether the shock was due to hæmorrhage or not

Dr W M Polk said that the exploratory incision, as practised in gynecological surgery, was a very simple affair, less free from danger than the opening of the pleural cavity, but he doubted whether such a very simple incision as those who confined their attention to this department frequently had to make would be sufficient in the class of cases now under discussion If it was necessary to introduce the hand and feel around among the intestines, a great deal was added to the risk, and the more the intestines had to be handled, the greater the danger would be

Dr W Gill Wylie said that he would have no hesitation in opening the peritoneum in any case where the patient's life was in question There was very little danger of increasing shock thereby, and if the shock was due to hæmorrhage, which was very likely to be the case, the prompt performance of laparotomy was urgently demanded for the purpose of checking this One of the principal dangers was from septic infection, and after performing operations in the abdominal cavity he not infrequently washed out the latter with a solution of bichloride of mercury, 1 to 10,000, following this with the injection of simple hot water

At a general meeting of the Academy held December 17, Dr T Gaillard Thomas read a paper on *Vaginal and Vulvar Enterocele* It was curious, he said, to note how very generally these varieties of hernia have been ignored in the systematic treatises, and this was the more remarkable since errors in their diagnosis were very liable to occur Of *vaginal enterocele* he said that it consisted in a descent of the intestines into the pelvic cavity, either in front of or posterior to the broad ligament, this descent always taking place obliquely A tumor finally formed in the vaginal canal, inverted one wall of that canal more and more completely, and might end by escaping from the vulva and hanging outside the body, as a complete prolapse of the bladder or rectum would do Under these circumstances it was evident that the tumor which protruded had for its component parts (1) the inverted vaginal wall, (2) the peritoneum, and (3) the intestines Later on in the paper Dr Thomas related a very remarkable case which had lately come under his notice, in which such a vaginal hernia hung down to the middle of the thigh, and in which, on account of the extreme sufferings of the patient, which had lasted for a number of years, he was induced to perform laparotomy When the abdominal walls had been cut through, an assistant in the meanwhile pressing the tumor up in the pelvis, he found, on a line with the symphysis pubis, a large soft tumor, which had probably been the original source of the trouble This he removed, securing the sac in the abdominal wound with sutures, and the patient made a good recovery Five weeks had now elapsed, and there had been no return of the symptoms which had formerly rendered the patient's life miserable, though he said that he still felt somewhat apprehensive of the future The tumor removed was examined by Dr H C Coe, the pathologist to the Woman's Hospital, and he expressed the opinion that it was probably an unusual growth of the pelvic connective tissue

Unquestionably the greatest danger attending vaginal, as well as pudendal and perineal hernia, arose from the possibility of an error of diagnosis on the part of an impulsive or unwary surgeon Vaginal hernia as long as it remained in the pelvic cavity, and did not interfere with parturition, was usually a matter of little moment Under certain malign influences, however, occurring during labor, as well as in the non parturient state, such as pressure from the fœtal head, inflammatory processes, fœcal impaction, torsion of the contents of the sac, or the existence of a neoplasm, strangulation might occur The symptoms which were then apt to develop were Difficulty in locomotion, pelvic tenesmus, dragging sensations, tendency to constipation, and, in time, vomiting Should the accident complicate parturition, obstructed labor was apt to result Upon vaginal examination a tumor of greater or less size was found in the vagina, and was diagnosticated by the following physical signs It is supple, soft and yielding, decreases upon pressure, gives a sense of gurgling to the finger, if not to the ear, increases upon the patient's coughing or straining, yields resonance upon percussion, and is very generally reducible if the patient is placed in the knee chest position and efficient taxis is practiced Error in diagnosis was likely to occur, Dr Thomas said, from the practitioner's being too confident, too much off his guard and too little inclined to consider the possibility of a mistake If he approached these cases calmly, philosophically, and in a proper spirit of diagnostic investigation, it was very improbable that the nature of the trouble would be misunderstood In certain rare instances acute vaginal hernia occurred as a consequence of some traumatic influence destroying the continuity of this canal in its upper part, and he related two such cases which had come under his own observation

Pudendal hernia demonstrated its existence by the presence of an elastic tumor about the middle of the labium majus of one side Having explained its mode of origin, he said that from inguinal hernia ending by descent into one of the labia majora the internal variety might thus be distinguished (1) The finger, pushing the tumor upward, will pass into the pelvic cavity between the ischium and vagina (2) At the level of the os uteri, or thereabouts, it will enter the pelvic roof (3) Pressure being maintained on the inguinal canal, and the patient being ordered to cough, it will, in spite of the pressure, recur The following conditions are mentioned as liable to be confounded with pudendal hernia Cyst or abscess of the vulvo vaginal gland, abscess of labium majus, fatty or fibrous tumors of the labium, tumors descending from the pelvic cavity The differentiation of pudendal hernia from these conditions of the labia should be very carefully considered, for if an erroneous diagnosis were made here, a fatal issue would probably be the result The diagnostic signs which proved most reliable, and which might almost be styled pathognomonic, were these (1) Airy feeling upon palpation, (2), gurgling upon replacement, (3), diminished tension in the dorsal decubitus, (4), diminution of bulk upon taxis, (5), resonance upon percussion, (6), succussion upon coughing, (7), intestinal pains of colicky character

Dr Thomas then went on to speak of perineal hernia This might affect both male and female, and in the latter it consisted of the descent of the intestines between the vagina and rectum, the advance being made posterior to the broad ligament, and continuing *until the perineal muscles are forced apart*, and the gut, with its peritoneal envelope, was arrested by the skin All these varieties of hernia were usually readily amenable to taxis, and this he had invariably found to be greatly facilitated by the knee chest position In some rare cases strangulation occurred, and under these circumstances the same surgical practice was indicated as in inguinal or crural hernia, viz cautious opening of the sac, and section of the constricting band by passing up a probe-pointed bistoury

In conclusion, he remarked that, unfortunately, little could be said concerning the treatment of vaginal or vulvar hernia, for the reason that there was but one variety, the pudendal, for which very much could be done That variety was amenable to treatment by the ordinary truss, as inguinal hernia was The other varieties could to a limited degree be relieved by pessaries, perineal pads, abdominal bandages, etc , but we were poor in methods of decided relief, and utterly wanting in those of cure It appeared to him that the plan suggested and partially carried out in the case of vaginal hernia which he had related promised more than any other which had been brought forward, but of the validity of this promise time and experience would have to give the proof He was certain that if another case of large vaginal hernia should present itself he should feel inclined to try laparotomy, dragging up the sac, and fastening it in the abdominal wound P B P

THE INTERNATIONAL CONGRESS

To THE EDITOR OF THE JOURNAL

Dear Sir —According to the *Medical News* (of Philadelphia) of December 26, "*The Medical Record* gives the following editorial note from the *St Petersburg med Wochenschrift*, of Nov 21 'The prospects of the next International Medical Congress, which *was* to meet in 1887, in Washington, have lately, in an unusual manner, been put in jeopardy The original Organizing Committee, of which, as announced by us in previous communications, *the well known Surgeon General of the U S Army was Secretary-General*, and to which the most distinguished American physicians belonged, has been retired This was accomplished through the intrigues and hostility which developed at the last annual meeting in New Orleans At this time a new Committee was appointed, *under the Presidency of a Dr Shoemaker*, of Philadelphia This new organization committee contains but a few of the members of the previous committee, and *is composed mostly of unknown and insignificant physicians*, who inspire no confidence in their capacity for conducting the Congress'"

When the *St Petersburg med Wochenschrift* knows no better than to confound "*the well-known Surgeon General of the Army*" with the officer who was the Secretary-General of the committee of seven, it publishes the value of its condemnation of the new committee as "composed mostly of unknown and insignificant physicians" To it they doubtless are unknown But what shall be said of both the *Medical Record* and *Medical News*, which reproduce this statement about "the well-known Surgeon General of the Army" (and not for the first time) without contradiction?

FIVE CASES OF PELVIC CELLULITIS TERMINATING IN ABSCESS[1]

BY AUGUSTUS P CLARKE, M D,
OF CAMBRIDGE, MASS

I have had several cases of pelvic cellulitis terminating in abscess The cases in the non puerperal state have usually resulted in resolution, but this has not been the invariable rule The most obscure and difficult to diagnosticate have been those of a chronic type or cases in which the constitutional symptoms were less pronounced, or cases in which pain was one of the leading symptoms Cases have occurred in which the urinary symptoms were at first the most troublesome Cases have occurred in which there was pain in the region of the hips, knees, an anxious countenance, chills, marked increase of temperature and of the pulse, alternations of sweating and partial recovery

In some cases careful vaginal examination at first failed to reveal the true cause of the symptoms This was so particularly in the case of Mrs G F S, aged 30 years, married, but who never had had a living child At the time I was called Mrs S had been married five years, she became pregnant, but miscarried at the fourth month Husband was of a healthy constitution and of regular habits I was first called on April 28, 1876 Mrs S complained of some pain in the region of the bladder and in the left groin She was sitting up She had had chills, but thought they were due to her sore throat—a slight attack of tonsillitis Next day, the 29th, the patient was better as regards her throat, but complained of her back, and of some disturbance in micturition The urine showed no indications of renal trouble There was a dragging sensation at the umbilicus On April 30 there was more pain in the bladder and great pressure felt in the pelvic region, there was some discomfort extending from the iliac region to the loins and to the umbilicus, and through the perineum and to the lower extremities A careful vaginal examination failed to disclose any marked or characteristic localized point of tenderness This examination was made on May 1 Subsequent examinations were made May 2, 3 and 4, but the appearances were not as yet well marked

The pain and urinary trouble, with very moderate constitutional disturbance, were the leading characteristics On May 5, 6 and 7 the pain in these parts was complained of as intolerable There were occasional chills, and each chill was invariably followed by profuse sweating Large and frequent doses of morphia were required The diagnosis was pelvic cellulitis with a probable formation of abscess There was, however, no fluctuation nor any marked swelling, but at times, by careful manipulation and firm pressure with the finger, I could elicit greater tenderness behind the uterus than in any other place Patient stated that she had been through a similar ordeal a year and a half before, but that there was no pus observed as occurring in that attack, that she was treated from time to time by an experienced physician, and was seen later in consultation by one of the leading members of the Massachusetts Medical Society, that her case at that time was not regarded as an abscess, but as a kind of uterine nervous affection

My visits were continued and the symptoms were essentially the same until May 16, when a small amount of purulent matter was found on vaginal examination, but no pain was discovered where it had been discharged The patient's symptoms were now easier, and by June 10 she was able to be up and about her house

On July 15 I was again called, and found that all of her old symptoms had again returned The pain, chills and sweating were the main symptoms She continued to suffer until July 30, when she began a speedy recovery During this attack there was no positive proof of suppuration, only a little muco purulent discharge which could be seen by very careful vaginal examination The uterus was not flexed, but was movable, though the cervix was drawn to the left side in consequence of the inflammation having occurred in the left broad ligament

On March 30, 1877, I was again called, when Mrs S had another attack after exposure during a drive in inclement weather She had just passed through her menstrual period when this attack began This attack lasted until May 16, when she was quite convalescent

The next attack began in August following I was called on August 17 This lasted until August 25, when she was able to be up and about the house During all these attacks subsequent to the first described, very little pus was seen, but the symptoms were essentially the same as at first There was no point discovered where pus was discharged, but it would probably be the result The diagnostic signs which proved most reliable, and which might almost be styled pathognomonic, were these (1) Airy feeling upon palpation, (2), gurgling upon replacement, (3), diminished tension in the dorsal decubitus, (4), diminution of bulk upon taxis, (5), resonance upon percussion, (6), succussion upon coughing, (7), intestinal pains of colicky character

---

[1] Read before the Boston Gynecological Society

Dr Thomas then went on to speak of perineal hernia This might affect both male and female, and in the latter it consisted of the descent of the intestines between the vagina and rectum, the advance being made posterior to the broad ligament, and continuing until the perineal muscles are forced apart, and the gut, with its peritoneal envelope, was arrested by the skin All these varieties of hernia were usually readily amenable to taxis, and this he had invariably found to be greatly facilitated by the knee chest position In some rare cases strangulation occurred, and under these circumstances the same surgical practice was indicated as in inguinal or crural hernia, viz cautious opening of the sac, and section of the constricting band by passing up a probe-pointed bistoury

In conclusion, he remarked that, unfortunately, little could be said concerning the treatment of vaginal or vulvar hernia, for the reason that there was but one variety, the pudendal, for which very much could be done That variety was amenable to treatment by the ordinary truss, as inguinal hernia was The other varieties could to a limited degree be relieved by pessaries, perineal pads, abdominal bandages, etc , but we were poor in methods of decided relief, and utterly wanting in those of cure It appeared to him that the plan suggested and partially carried out in the case of vaginal hernia which he had related promised more than any other which had been brought forward, but of the validity of this promise time and experience would have to give the proof He was certain that if another case of large vaginal hernia should present itself he should feel inclined to try laparotomy, dragging up the sac, and fastening it in the abdominal wound P B P

THE INTERNATIONAL CONGRESS

To the Editor of the Journal

Dear Sir —According to the *Medical News* (of Philadelphia) of December 26, "*The Medical Record* gives the following editorial note from the *St Petersburg med Wochenschrift*, of Nov 21 'The prospects of the next International Medical Congress which *was* to meet in 1887, in Washington, have lately, in an unusual manner, been put in jeopardy The original Organizing Committee, of which, as announced by us in previous communications, *the well-known Surgeon General of the U S Army was Secretary-General*, and to which the most distinguished American physicians belonged, has been retired This was accomplished through the intrigues and hostility which developed at the last annual meeting in New Orleans At this time a new Committee was appointed, *under the Presidency of a Dr Shoemaker*, of Philadelphia This new organization committee contains but a few of the members of the previous committee, and *is composed mostly of unknown and insignificant physicians*, who inspire no confidence in their capacity for conducting the Congress'"

When the *St Petersburg med Wochenschrift* knows no better than to confound "*the well-known Surgeon General of the Army*" with the officer who was the Secretary-General of the committee of seven, it publishes the value of its condemnation of the new committee as "composed mostly of unknown and insignificant physicians" To it they doubtless are unknown But what shall be said of both the *Medical Record* and *Medical News*, which reproduce this statement about "the well-known Surgeon General of the Army" (and not for the first time) without contradiction? SURGEON

MISCELLANEOUS

THE PHILADELPHIA POLYCLINIC —The new building for the Philadelphia Polyclinic College on Broad Street will soon be ready for its occupants The building will contain more hospital wards and private rooms for pay patients, and the dispensary service will be given more attention

FIVE CASES OF PELVIC CELLULITIS TERMINATING IN ABSCESS[1]

BY AUGUSTUS P CLARKE, M D,
OF CAMBRIDGE, MASS

I have had several cases of pelvic cellulitis terminating in abscess The cases in the non puerperal state have usually resulted in resolution, but this has not been the invariable rule The most obscure and difficult to diagnosticate have been those of a chronic type, or cases in which the constitutional symptoms were less pronounced, or cases in which pain was one of the leading symptoms Cases have occurred in which the urinary symptoms were at first the most troublesome Cases have occurred in which there was pain in the region of the hips, knees, an anxious countenance, chills, marked increase of temperature and of the pulse, alternations of sweating and partial recovery

In some cases careful vaginal examination at first failed to reveal the true cause of the symptoms This was so particularly in the case of Mrs G F S, aged 30 years, married, but who never had had a living child At the time I was called Mrs S had been married five years, she became pregnant, but miscarried at the fourth month Husband was of a healthy constitution and of regular habits I was first called on April 28, 1876 Mrs S complained of some pain in the region of the bladder and in the left groin She was sitting up She had had chills, but thought they were due to her sore throat—a slight attack of tonsillitis Next day, the 29th, the patient was better as regards her throat, but complained of her back, and of some disturbance in micturition The urine showed no indications of renal trouble There was a dragging sensation at the umbilicus On April 30 there was more pain in the bladder and great pressure felt in the pelvic region, there was some discomfort extending from the iliac region to the loins and to the umbilicus, and through the perineum and to the lower extremities A careful vaginal examination failed to disclose any marked or characteristic localized point of tenderness This examination was made on May 1 Subsequent examinations were made May 2, 3 and 4, but the appearances were not as yet well marked

The pain and urinary trouble, with very moderate constitutional disturbance, were the leading characteristics On May 5, 6 and 7 the pain in these parts was complained of as intolerable There were occasional chills, and each chill was invariably followed by profuse sweating Large and frequent doses of morphia were required The diagnosis was pelvic cellulitis with a probable formation of abscess There was, however, no fluctuation nor any marked swelling, but at times, by careful manipulation and firm pressure with the finger, I could elicit greater tenderness behind the uterus than in any other place Patient stated that she had been through a similar ordeal a year and a half before, but that there was no pus observed as occurring in that attack, that she was treated from time to time by an experienced physician, and was seen later in consultation by one of the leading members of the Massachusetts Medical Society, that her case at that time was not regarded as an abscess, but as a kind of uterine nervous affection

My visits were continued and the symptoms were essentially the same until May 16, when a small amount of purulent matter was found on vaginal examination, but no pain was discovered where it had been discharged The patient's symptoms were now easier, and by June 10 she was able to be up and about her house

On July 15 I was again called, and found that all of her old symptoms had again returned The pain, chills and sweating were the main symptoms She continued to suffer until July 30, when she began a speedy recovery During this attack there was no positive proof of suppuration, only a little muco purulent discharge which could be seen by very careful vaginal examination The uterus was not flexed, but was movable, though the cervix was drawn to the left side in consequence of the inflammation having occurred in the left broad ligament

On March 30, 1877, I was again called, when Mrs S had another attack after exposure during a drive in inclement weather She had just passed through her menstrual period when this attack began This attack lasted until May 16, when she was quite convalescent

The next attack began in August following I was called on August 17 This lasted until August 25, when she was able to be up and about the house During all these attacks subsequent to the first described, very little pus was seen, but the symptoms were essentially the same as at first There was no point discovered where pus was discharged, but it was believed the pus escaped from the posterior "cul de sac" or from behind the uterus. Most that could be seen by careful vaginal examination with a Sims's speculum was a small amount of purulent matter in the vagina and posterior to the cervix. There was, however, no cervicitis nor any laceration nor ectropion of the cervix. There was no large tumor indicative of a great collection of pus, but the length of the time during each attack, the chills, the sweating, the high temperature, which often reached 103° F., and the pain and general disturbance of the whole organization indicated suppuration. Such, in fact, was my diagnosis as expressed to the patient and her family.

---

[1] Read before the Boston Gynecological Society

After recovering from this attack she remained well as usual until some time after—the middle of April, 1878, when she was again seized with her old symptoms, but having removed from Cambridge, she was induced to call in an eminent surgeon of the Boston City Hospital. This surgeon saw the patient several times until May 4, when I was again called to take charge of the case. The patient was a great sufferer. On my first visit the nurse informed me that her previous medical attendant wholly disagreed as to my diagnosis, and stated that it was his opinion the patient had never suffered from an abscess of the pelvis, that there were no indications of the formation of any pus, though in his examination of the patient he did not make use of the speculum as an aid in the diagnosis.

May 6, by the help of Sims's largest speculum, and by the advantage of good sunlight, I was fortunate enough, with the assistance of the nurse, to discover the point where fluctuation appeared. By means of a small trocar and bistoury I let out a large amount of fetid pus, to the patient's speedy and great relief. There was never any escape of pus into the rectum. The patient subsequently removed from the vicinity of Boston and thus wholly passed from my care. I learned that she suffered from a subsequent attack, but have had no special knowledge of the sequelæ of her case. The cause of this case was no doubt a pelvic hæmatocele, or some accident to the perimetric cellular tissue during the time of an abortion, which occurred soon after marriage.

Case 2.—Another case I was called to attend on September 28, 1870. This was an unmarried woman, Miss L., aged 16 years. She had been confined to bed for several days previous to my first visit. She had suffered from a severe exposure during a wet day immediately after having menstruated, which happened some two weeks previous to my first visit. Owing to her youth and being unmarried she deferred calling in medical aid until the pain became very severe. She had suffered from repeated chills, each followed by a good deal of febrile disturbance and general prostration. My next visit was on September 29, when the greatest pain was felt in the rectum, with pain shooting down through the perineum. This was controlled somewhat by the administration of full doses of opium.

On October 1 a large discharge of fetid pus escaped by the vagina. The opening occurred somewhat behind the uterus, but more to the right. There was great difficulty in making a satisfactory vaginal examination, owing to the narrow and unyielding state of the vagina. The patient quickly recovered, married, and became pregnant, but before the close of her term she was seized with uræmic convulsions. I succeeded in effecting an early delivery, but the case terminated fatally. The cervix, after recovery from the cellulitis was drawn to the right, owing to the inflammation in the right broad ligament. This case was evidently caused by a pelvic hæmatocele occurring immediately after menstruation, that instead of being absorbed, the mass softened and became purulent. The pus was so perfectly discharged that operative interference became unnecessary.

Case 3.—Another patient I was called to attend on April 29, 1883. Her age was 42 years, and she was the mother of three children, and had been married seventeen years. The youngest child was 12 years old. She had never before had any severe sickness, and had recovered well after each time of confinement. Never had suffered from laceration of the cervix uteri, nor of the perineum. At the time I was called she was suffering a good deal from tenderness about the uterus, and from severe pelvic pain. She also suffered from dysuria, and a feeling of bearing down and pressure on the rectum. As she had been troubled from the presence of hæmorrhoids or from irritation about the lower portion of the rectum, it was hoped that by the application of ligatures to the bleeding piles and by rupturing the sphincter ani the patient would make an early recovery. This operation only gave temporary relief, for after a short time her former symptoms returned with increased violence. She had severe pain, frequent chills, followed by high temperature, which for several days maintained points varying from 101° to 103.5° F. She also suffered greatly from exhausting sweats. The patient became so reduced for a while as to resemble a person in the advanced stage of phthisis. She was confined to her bed, and was able to take but little nourishment. The uterus was immovable, and the whole pelvic vaginal roof became hard and unyielding, and gave no indication of a point of suppuration. All the while the dysuria was great, and the urine had to be drawn by the catheter. Pressure on the rectum was bitterly complained of. Heroic doses of opiates in various forms were required for her relief, and even then she was made only partially comfortable.

This state of things continued until May 30, when a swelling appeared just above Poupart's ligament on the right, and I made a free incision down to the pus. The opening continued to discharge for some days, during which time an ordinary probe could be passed five inches towards the pelvis. On June 5 fluctuation appeared behind the uterus on the left, this was incised. Both these openings were frequently washed with a weak solution of carbolic acid and thymol. Small quantities of the latter were frequently injected into the sinuses, and into the pus cavity. The pain at length ceased, and by July 13 the patient was able to be up on a lounge, and both openings had closed.

August 27.—Vaginal examination showed that the abscess had contracted and cicatrized, and the uterus had become quite movable again The cervix was not drawn to either side, though the uterus had not fully ascended to its normal position

Here we evidently had inflammation of both broad ligaments The patient was then free from hæmorrhoids and had full and easy dejections She had fully recovered the use of the sphincter ani She was in good health, was regaining her strength, and her weight was 180 lbs This attack of cellulitis was undoubtedly brought on by the presence of internal hæmorrhoids,' and by the tenesmus from a contracted and rigid anus from which she had suffered for several years

Case 4 —Mrs R , aged 30 years I was in attendance from April 13 to June 27, 1879 In this case there was prolonged constitutional and local suffering The patient was finally able to be about again, but the uterus was fixed and the cervix drawn to the left There developed three years ago a marked cystocele and partial rectocele which for awhile I succeeded in some measure in relieving by an inflated rubber-disk pessary This lady was the mother of two children, but no marked laceration of the cervix or of the perineum occurred during her labors The cellulitis must have been induced by an attack of gonorrhœa contracted from an unfaithful husband The purulent matter must have passed up into the left Fallopian tube, and there excited the inflammation which produced such disastrous consequences She never recovered from the pelvic displacements An operation for ample closure of the vulva was undertaken for her relief in 1884, but this was only partially successful, for the united surfaces of the labia were constantly irritated by the continual displacement of the organs downwards The patient finally suffered from hæmoptysis, and died from local and constitutional disturbance during the early part of the year 1885

Case 5 —On June 11, 1872, I was called to attend Mrs T , aged 36 years She had recently moved from Portland, Maine, where some two years before she suffered from an attack of pelvic cellulitis, which terminated in abscess She at that time was under the care of the late Dr Greene, of that city She had been married eight years, but had never been pregnant She had stenosis of the cervix uteri, and suffered from dysmenorrhœa I continued to attend her from June 11 to July 3 of that year (1872) During this attack she suffered severely from pain and serious constitutional symptoms, and a pelvic abscess formed posterior to and to the left of the fundus uteri, the place where the former one had evidently occurred The abscess was high up and difficult to reach, but large quantities of fetid pus began to flow on June 28, and within a few days I was able to find the point of discharge This I enlarged so as to be able to insert the index finger and explored the cavity The lining membrane was rough and jagged An application of a solution of silver nitrate, ʒj—℥j, was made daily for several days, when the discharge ceased, and the cavity contracted and at length cicatrized I saw the patient on September 15 and November 27 following, when she called at my office There was then no discharge, and she was becoming quite strong again The uterus was raised up in the pelvis, and was somewhat retroverted, but it gave her no marked inconvenience The uterus was also fixed and tilted somewhat (the fundus) to the left

I heard from this patient two years afterwards and she was in her usual good health She had then left the State The cause of this attack I could not fully ascertain, but I believe it must have been in consequence of an attempt at dilatation of the contracted cervix uteri as a means of treatment for the stenosis This lady had been under the care (?) of an enthusiastic gynecologist but a short time previous to coming under the treatment of Dr Greene

THE EFFECTS OF COCAINE ON THE CENTRAL NERVOUS SYSTEM[1]

BY D R BROWER, M D

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM IN THE WOMAN S MEDICAL COLLEGE OF CHICAGO AND LECTURER ON PRACTICE OF MEDICINE IN RUSH MEDICAL COLLEGE (Spring Course)

We have recovered from the primary effects of the brilliant discovery of Dr Carl Koller, that sixteen months ago electrified the medical world, and can now reason together calmly and dispassionately about this powerful therapeutic agent

I have been using in private and hospital practice the preparation of the coca leaf for about six years, and for about one year past the alkaloid cocaine, and have reached certain conclusions as to its beneficial and its baneful effects on the central nervous system, that I propose to present for discussion in this paper I say beneficial and baneful effects, for my first proposition is, that it is as powerful for evil as it is for good

First Its effect upon the brain —In small doses, that is, three or four drachms of the infusion, or one-half to one grain of the alkaloid, it is one of the most certain and agreeable of all cerebral stimulants It increases the frequency of the pulse and respiration, and elevates the body temperature It gives a sense of well-being, a freedom from care, and a pleasant mental exaltation The first effect of the drug is upon the cerebrum, then upon the medulla oblongata, the sense of mental exhilaration preceding the stimulation of respiration and circulation In small doses it also stimulates the spinal cord producing a desire for muscular activity, and an increased activity of the reflexes

The effects upon the spinal cord, according to the experiments of Dr Alexander Bennet,[2] are due entirely to its action upon the posterior column of the spinal cord, an observation that may make the drug useful in locomotor ataxia I am now making clinical investigation in this direction

This increased activity of the central nervous system is usually followed by a quiet, composed, self-satisfied condition of the mind and body that eventuates in sleep These agreeable effects are accompanied with loss of appetite, frequently with nausea, constipation and diminished activity of the kidneys, of the sexual functions, and of the skin In large doses, two to ten grains of the alkaloid, there are produced tinnitus aurium, photophobia, illusions, hallucinations, great loquacity, and a marked tendency of the mind to exaggeration and misrepresentation If continued for some time this dose produces perversion of the affections, a disturbance of the moral emotions, a tendency to quarrel with friends and former associates, and to form alliances with persons formerly regarded as inferiors

---

[1] Read before the Chicago Medical Society Jan 4 1886

[2] British Medical Journal April 18 1874

This state of the nervous system may become very like delirium tremens, with the same kind of muscular tremor, and the same kind of horrible hallucinations During this time the loss of appetite and diminished activity of assimilation result in extreme pallor of the face, dryness of skin, extreme constipation, very much diminished urinary excretion, loss of sexual function, and great emaciation

Second Cocaine in the Alcohol and Opium Inebrieties —Much has been written upon the use of this drug in efforts to cure this form of nerve mal-nutrition Louis Bauer, M D,[1] in an admirable article details his experience with it in a case of alcohol inebriety He began with one fifth of a grain, which the patient soon increased to ten grains by hypodermic injection, with the same disastrous result upon the nervous system as has been mentioned, but he expresses the opinion that the cocaine inebriety was less objectionable than the alcoholic

Dr Erlenmeyer[2] gave it, in various doses, in 236 cases of opium inebriety, and expresses sentiments that entirely agree with my own He says that while cocaine does modify and mitigate the phenomena of opium abstinence, its effect is only transient and of brief duration, he regards it of trifling value as a substitute for morphine

Dr J T Whittaker[3] reports, in an elaborate paper, the results from its hypodermic use in two cases of opium inebriety that were satisfactory Dr Palmer, of Louisville, Ky, who was one of the first to advise its use in such cases, continues to be an enthusiastic advocate of the drug

My own experience is against its use in either of these inebrieties; it undoubtedly makes the withdrawal of either of these agents much easier for the patient, because its effects are so similar to opium and alcohol that he scarcely feels the need of either, but you place within his reach an agent much more rapidly disastrous and destructive to the nutrition of the cerebral convolutions, an agent that will soon sink him to a degradation much lower than is possible with either of the others

Third Cocaine in Melancholia —The best results yet obtained from the administration of the drug have been in conditions of mental depression Dr Jerome K Bauduy,[4] in a valuable paper read before the American Neurological Society, June 17, 1885, relates a very extensive experience with the drug in melancholia His method is to inject one grain of the muriate of cocaine, and he frequently witnesses the morose, silent, taciturn patient, a prey to the most profound grief or sadness, recover his normal self, begin to talk about his case and wonder how he could ever have experienced such gloomy ideas He reports one case of suicidal melancholia which recovered in less than one month, and to whom he only gave five injections of cocaine Dr Alex B Shaw,[1] in an able paper on the uses of the drug, speaks with the same degree of positiveness of its value in the insanities with depression

My own experience, with cocaine, in this form of insanity is in accord with Drs Bauduy and Shaw Although the bad effects of the drug upon the digestive and assimilative processes, and upon the secretions, have frequently disappointed me in its use I have observed their valuable suggestion of giving the drug several hours before eating, in order to avoid the anorexia and nausea, but even with this precaution I have frequently found it impossible, while using it, to give that great abundance of food, that systematic feeding, which after all, is the most valuable therapeutic measure in the relief of melancholia

Then again the excretory organs are often at fault, indeed often the foundation of this form of insanity, the mal-nutrition of the brain being due to the accumulation in the blood of the waste products of tissue metamorphosis In such cases the further depression added to this by cocaine, must more than counteract the beneficial effects of the cerebral stimulation In such cases alteratives and stomachic tonics added to the treatment may make it successful

I recall two cases of profound melancholia One, a physician, aged 45, from a neighboring town of this State, an uncomplicated case, the result of excessive professional work in a large country practice He received the cocaine in one grain doses three times a day, with pil hydrargyri, aloes and strychnia His recovery was rapid, and has continued for four months The other case was that of a woman, aged 48, from Indiana, laboring under melancholia, that seemed to have its origin in the fret and worry induced by a tumor of one of the mammary glands Under this combined treatment recovered about as rapidly as the case detailed by Dr Bauduy In both these cases the drug was administered in pill form, and probably because of its combination did not interfere with the free use of egg-nog and other concentrated food in large quantities

I have now under treatment a case of melancholia in which I am using the drug with the atomizer, using about four grains a day, on the nasal mucous membrane The stimulating effects on the brain are manifested in a very few minutes after it is used I am of the opinion that cocaine is the most valuable recent addition made to the therapeutics of melancholia, especially if its bad effects are guarded against in the way suggested

Fourth Neurasthenia —Cocaine is of value in the treatment of this tedious and perplexing derangement of the nervous system Dr J Leonard Corning,[2] in his scientific review of the cerebral form of this disease, calls it "the remedy *par excellence*"

[2] Brain Exhaustion

Dr William Oliver Moore,[1] in a very valuable paper on the physiological and therapeutical effects of coca and its alkaloid, gives his personal experience and the observations of others as to the value of the drug in all depressed conditions of the nerve centres, as well as its effects upon himself in various doses

My experience coincides with the testimony of these writers, but I observe the same care in sustaining the digestive function and stimulating the eliminations as stated before Cocaine as mentioned in the beginning of this paper, is as powerful for evil as for good, and it requires no special prophetic gift to say that more disastrous results will be experienced by the laity from its indiscriminate use, than have been known from either opium or alcohol Indeed, its action upon some persons in moderate doses is alarming Dr G W Kinnicutt relates a case of poisoning from three and a third grains of the drug applied to the nasal mucous membrane, in the case of a female aged twenty-five, who had been using it for hay fever When he arrived she was in an alarming comatose condition, from which she recovered in about three hours, under the liberal use of brandy, ammonia and digitalis, with heat to her extremities and epigastrium

Dr J Spear,[3] U S Navy, publishes a case of profound coma closely simulating opium poisoning, in a private, U S M C, aged twenty nine, the result of the hypodermic use of ten grains in divided doses, extending over about twelve hours The case was supposed to be opium poisoning, and was treated with atropia, coffee, and flagellation, and in about nine hours he recovered from the immediate effect of the poison Dr T H Burchard[4] gives an account of a case in which the hypodermic injection of four-fifths of a grain produced a sudden and complete loss of consciousness, and in which respiration stopped, and the radial pulse was scarcely perceptible Artificial respiration, hypodermic injection of one twelfth grain of atropia, and sinapisms to heart and extremities, relieved the patient Fifteen minutes after the prostration the pulse was forty-eight and feeble, the respiration seven or eight, and the pupils contracted Unconsciousness continued about twenty minutes

Dr Merriam[5] relates the case of a gentleman who had been taking cocaine for four months for sick headache beginning with about two grains a day, and gradually increasing till he was taking from ten to fifteen grains daily He was very weak, with a pulse of 100, and his mind wandering somewhat as in delirium tremens Drs Bauduy and Shaw, in their papers already mentioned, dwell especially upon the dangers of the continued use of the drug in large doses My experience is in accord with these several observers Several cases of the poisonous effects of the drug have been under my treatment during the past six months, and I will call the attention of the Society to two of these cases, both physicians

First The case of Dr W, aged about thirty, of excellent physique, of neurotic tendency by inheritance, who began the use of the hydrochlorate of cocaine upon the nasal and pharyngeal mucous membranes for hay fever He gradually increased the dose to five grains taken in one dose in the evening, when his attack of hay fever was usually most distressing This dose gave almost immediate relief from the hay fever, and gave a sense of mental stimulation very like champagne He was almost at once seized with a desire for brain work, and would pass the greater part of the night reading and writing on professional topics, experiencing a keenness of perception and a mental vigor greater than normal He describes his sensations during the period of activity of the drug as exceedingly delightful Towards morning he would fall asleep, and on the next day he would have no appetite and but little desire for work, the excessive stimulation having been followed by a corresponding depression of the vital forces

He soon had a very irregular and rapid action of the heart, and passed by rapid stages to a condition of deplorable neurasthenia, from which he is now slowly recovering He had the same derangement of digestion, assimilation and elimination that have been already mentioned He had but little desire for food, a thickly coated tongue, a feeble digestion, considerable emaciation, urine scanty, and much of the time loaded with uric acid and urates, with dyspnœa and the irregularity of heart action before mentioned The stools for some time were chalky, skin dry and pallid, pupils dilated, reflexes, especially the patellar tendon, much increased, and muscular powers much diminished

He continued the use of the drug about ten days, and stopped it because he feared its enslaving power The profound depression of the nervous system followed immediately upon its stoppage The agents used to overcome this neurasthenia were an abundance of easily digested food, mild alteratives, moderate alcoholics, strychnia in small doses, cinchona, and the compound syrup of hypophosphites As stated, the depression is gradually passing away, but the ten days' use of cocaine has incapacitated him for four months from the practice of his profession, and the probability is that at least three months more will be required to complete his restoration

Second The case of Dr B, aged thirty five, a man of decidedly neuropathic temperament, a hard working, conscientious, and skilful physician, in the enjoyment of a fair but very laborious practice, with an excellent family history Three years ago, with my assistance, he discontinued the use of opium, which he had been using excessively He began the use of cocaine last May in one-eighth grain doses, having been led to believe it to be a harmless stimulant, and being, at the time, much run down by excessive professional work It gave him such a sense of well-being as he had never experienced from any drug before, the sense of complete repose and self-satisfaction it produced being very much more marked and agreeable than that derived from opium He gradually increased the dose until he consumed about fifteen grains a day by hypodermic injection The large doses soon began to produce mental disturbance, he became irritable, quarrelsome, impetuous, and considered himself to be possessed of a mission, and that to revolutionize the medical practice, claiming to be able to cure all diseases by the potency of cocaine He gave it indiscriminately to all his patients He gave it to obstetric cases and to syphilitic cases He gave it to his wife, his three children and his mother He was formerly a modest man of science, he became bold and unscientific in his method, went about engaging in lawsuits, carrying a pistol and frequently brandishing it in public places, threatening vengeance upon all who dared to doubt the correctness of his various extravagant statements, a perfect terror in his neighborhood He had been a very devout member of the Roman Catholic Church, but the priest of the church could now do nothing towards restraining his wild impetuosity He neglected his practice and by his manner alienated those whom he did not neglect, so that very soon he lost it Piece by piece his horse, his buggy, and his furniture disappeared, until his family was reduced to poverty My repeated efforts to persuade him to stop the use of the drug were unsuccessful, indeed, simply resulted in making me the recipient of his wildest denunciations and of his severest threatenings Several physicians and druggists who made attempts to restrain him met with an equally positive rebuff The same general deterioration as before noticed, was manifest in his case, extreme pallor and dryness of skin, great emaciation, loss of appetite and no desire for sleep, so that for at least one week he did not assume the recumbent position

---

[1] Quarterly Bulletin New York Post Graduate School Vol I No 1

[2] Chicago Medical Journal Oct 1885

[3] The Medical Record Nov 14 1885

[4] The Medical Record Dec 5 1885

[5] Quoted by the Medical Record, Nov 28 1885 from Ohio Medical Journal

He continued to go from bad to worse until his *friends thought it best to restrain him* In pursuance of this object Dr F L Wadsworth and I appeared before the County Court and advised his removal to the Washingtonian Home Here the cocaine was gradually withdrawn, but his mental extravagance continued unabated He left this institution clandestinely, and is now supposed to be in Canada

To sum up

1 Cocaine in small or moderate doses is a cerebral stimulant, but produces derangement of the digestive and assimilative functions, and diminishes the elimination of waste

2 The use of cocaine in the alcoholic and opium inebriates is not satisfactory, while it is a more or less perfect substitute, yet its use is attended with greater danger than alcohol or opium

3 The use of cocaine in mental depression, if we carefully guard against the depressing effects of the drug upon digestion and assimilation, will often give better results than any drug hitherto used

4 The use of cocaine in neurasthenia is a valuable addition to the treatment

5 The drug, if administered in large doses persistently, causes a very marked deterioration of the central nervous system, producing a profound cerebral neurasthenia, and may produce such a mal nutrition of the cerebrum as to develop insanity

6 Cocaine, occasionally, in doses *heretofore* regarded as small, produces alarming depression of the central nervous system

SOME CASES OF REFLEX NEUROSIS[1]

BY G M GARLAND, M D ,

OF BOSTON, MASS

The subject of reflex neurosis is one of great interest, and the cases which come under this grouping, present such diversity of phenomena and such eccentricities of behavior that they are always fascinating to the observer The following cases presented themselves at the Carney Hospital, and were there treated during my service in the summer of 1885 They appear to me to be worthy of record

Case I —M I D , merchant, aged 58, entered the hospital on July 7, 1885 He had been suffering for six weeks with severe supra orbital neuralgia on the right side The pain was not continuous, but seized him at frequent intervals every day Each individual attack was of short duration, but the severity was so great and the patient's dread had become so exaggerated that he was completely unmanned He had lost flesh, strength and appetite, and he was nervous to an extreme degree He had been obliged to give up his business, and he emphasized the apprehension with which he awaited each attack His tongue was heavily coated and his bowels were constipated

Upon questioning, it was learned that the patient had had an attack of neuralgia in the same spot three years previous That attack was of short duration, however, and had never troubled him until it began at this time He was a man of free habits as regards food and drink He had always enjoyed good health up to last April, when he had pneumonia, which ran an ordinary course and terminated by complete res*olution His neuralgia began within a few weeks* after his recovery from the pneumonia His face presented a striking contrast between a high color on the cheeks and a zone of waxy pallor round his eyes

Physical examination revealed the following facts His heart, lungs and kidneys were sound There was no tenderness or swelling over the right supra orbital region His eyes were normal in appearance, and a later ophthalmoscopic examination by Dr Derby revealed merely a slight hypermetropia, which was fully compensated for by the glasses which he wore Nothing abnormal was found in his nostrils or mouth On opening his mouth, however, to exhibit his teeth, he excited an explosion of pain The right eye closed, tears ran from it and the lids trembled convulsively The face flushed and the mouth was drawn toward the painful side This attack lasted from one quarter to one-half a minute The patient then stated that he could produce these attacks by certain movements, which he avoided as much as possible Chewing his meat at table, drawing his shirt over his head, and certain other acts, would start the pain The examination of the ears was next in order, and these were found packed with hardened wax The right ear was so tightly plugged that it required nearly an hour of syringing before the mass was dislodged The left ear was cleansed *in a few minutes*

---

[1] Read before the Section for Clinical Medicine Pathology and Hygiene of the Suffolk District Medical Society December 9 1885

The fact that the patient could explode attacks of nervous force at will, by the movement of parts remote from the seat of the pain, led me to the belief that there must be a mechanical cause for the pain, and that I had discovered the cause in the impaction of the right aural canal. Accordingly, I stopped all the quinine and other powerful neuralgic medicines which he had been taking, and gave him simply one-twentieth of a grain of podophyllin before each meal to stimulate his digestive secretions.

The removal of the wax caused no pain or discomfort during the operation, and it was followed by an absolute cessation of the neuralgia for eleven days. Once or twice during these eleven days the patient reported a peculiar sensation over the right side of his forehead. It was not pain, but a sort of twitchy feeling in the skin. This aroused his apprehension again, but he was calmed by encouraging words and was told that time was required to cool the stove after the fire was out. On July 17 he sat and read in the sun for some time, and then experienced a mild attack of neuralgia. The pain differed from his previous attacks in that it was slight, and it persisted for ten or fifteen minutes. The house physician, Dr. Gleason, applied galvanism to his forehead, and this immediately relieved him.

Since that day he has had no other attack of pain; occasionally he would feel the twitching of the skin, referred to above, and to relieve this galvanism was applied eight or ten times. After leaving the hospital the patient took a trip to Europe, and has now returned to his business in perfect health.

There are several interesting points in connection with this case. The first is to trace out the nerve circuit between the ear tube and the supra orbital region. Dr. Hilton shows, in his work on "Rest and Pain," that the "upper and anterior part of the external ear and the auditory canal derive their sensibility from the fifth cerebral nerve," so that these portions of the ear are thus included in the sensory circuit with the forehead, temple, face, eyes, nose, teeth and tongue. The entire posterior surface and the anterior surface of the pendulous portion of the ear are supplied by branches from the second cervical nerve. The presence of wax in the ear tube seems a slight cause for so much distress, and yet if one will put his finger in his ear while making masticatory movements of the lower jaw, he will see that the wall of the canal is thereby moved in a forcible manner. Moreover, the history of a previous attack of neuralgia in the same region would lead one to assume an exaggerated susceptibility of the right supra orbital nerve. The future history of this case will be interesting.

The gradual cooling down of the excited nerve after the removal of the irritating cause was also an extremely interesting phenomena. For a number of weeks the patient complained of the twitching feeling described above, and such sensations always aroused his apprehensions.

Case 2.—This case exhibits a reversal of the nerve currents as compared with the previous one.

Miss C. P., aged 32. Entered the hospital June 18, 1885, with the history of a sore mouth since the preceding Friday, together with anorexia and vomiting. The mouth presented the familiar signs of mercurial salivation, with swollen gums and ulcerations. The patient complained of a sharp pain immediately behind the ears. A suitable mouth wash was prescribed and her gums rapidly improved. My term of service beginning in July, the previous treatment was continued until July 13, when my attention was especially attracted by a look of distress on her face, and by her complaints of a severe ear-ache on the left side which prevented sleep and was wearing out her strength. She said her ear had ached more or less from the time of entering the hospital, but it had grown much worse of late. In examining the ear nothing abnormal could be discovered outside or inside, and there was no tenderness to touch or upon percussion over the mastoid process. Between the anterior edge of the left steno mastoid muscle and the posterior edge of the ramus of the jaw there was a small spot very tender to pressure.

The mouth was next examined. The gums were everywhere healed, except around the left wisdom-tooth. Here the mucous membrane was swollen and pushed forward so as to conceal more than half of the tooth. On lifting this swollen tissue an ulcerated surface was exposed which was very tender to the touch. A small piece of lint, powdered with iodoform, was inserted between the gum and the tooth, and this constituted the entire treatment. Within two days the gum had receded almost to its natural position. The ear-ache was fast disappearing, and the patient could sleep. On the third day the dressing was omitted by mistake and the pain and sleeplessness returned. The lint was resumed. In two days more the ear-ache was entirely gone, and the patient was discharged well at the end of a week.

Case 3.—M. P., aged 68, entered the hospital June 20, 1885. Had been a sailor and fisherman for years. Ten months ago he contracted a cold and had been troubled with cough and dyspnœa since then. He is frequently awakened suddenly at night and is obliged to sit up gasping for air. During the day he has occasional paroxysms of severe dyspnœa, and his breathing is habitually rapid and labored. His face wears a distressed, weary look. Slight movements cause distress for breath, and he walks about with difficulty. The expectoration was a greenish-yellow, occasionally streaked with blood.

Physical examination revealed sibilant and sonorous râles over both chests, front and back. The inferior boundaries of the lung reached lower than normal, showing emphysematous enlargement. There were no signs of any pulmonary consolidation. Twenty years ago the patient's nose was bent toward the right side by a blow from a ball. Since the beginning of his cold he has noticed that he could not breathe through the right nostril.

From the date of his entrance until July 6, the patient was treated by various remedies addressed to his cough and to his asthmatic breathing, but no relief had been granted him. On July 6, I made an examination of the patient and found that his right nostril was packed with polyps. These polyps were four in number, large and firm in consistency. After two of them had been removed the patient experienced decided relief from his suffering and slept with comfort This improvement was still more increased after the removal of the remaining polyps at a later sitting All medication directed to his cough was stopped, and he was given some soda powders for his stomach, and an occasional laxative

The record for July 29 states that the moist râles heard at the previous examination had disappeared Only a high pitched sibilant râle could be heard occasionally on the left apex On violent respiration a few wheezy râles could be heard over the lowest part of the lung in front

During August, cocaine and glacial acetic acid were applied occasionally to the lower turbinated bones in both sides No other treatment has been employed since then, and within a few days the man reported himself to me in excellent condition He works about the hospital, goes up and down stairs at will, and breathes with ease Rarely he has an attack of asthmatic breathing at night

Case 4 —This was a peculiar case of laryngeal neurosis, which I was unable to trace to any local cause M A G , aged 39, unmarried, entered the hospital on September 8 She has always been a hard worker, but remarkably healthy Last December, after exposure to cold, she began to cough There was no expectoration then or at any time since She now grew somewhat hoarse This symptom varied at first, but finally increased in intensity until she could speak only in a whisper, and this aphonia has persisted up to the time of treatment at the hospital The cough was of a distressing, barking character, and persisted through all her waking hours at the rate of twelve to eighteen or twenty times per minute On retiring at night she would lie and cough for an hour or two before she could go to sleep The cough began by an audible sharp inspiration, as if the diaphragm contracted spasmodically, and this was followed by one or two loud expiratory barks The patient's hands and feet were restless, but exhibited no choreic movements or trembling Patient says she has lost forty pounds of flesh since she began coughing Her appetite is poor, and she complains of a dull, aching pain at the left side of the back after coughing

A careful physical examination was made There was no tenderness or tumefaction about the larynx The cords were slightly reddened, but were not paralyzed The throat and pharynx were considerably reddened by the rasping cough The lungs, heart, kidneys, ovaries and womb were normal The bowels were constipated, but yielded readily to laxatives Inasmuch as nearly every strong tonic had been tried upon the woman during the months of her affliction without any apparent benefit, it was thought advisable to try the effect of an ice-bag upon the spine Accordingly, on September 10, the bag was applied for two hours On the next day and thereafter it was applied for four hours daily

The hospital record, kept by Dr Gleason, reports the following progress

September 13 Patient coughs only when excited or nervous, and then only at long intervals The cough is no longer loud and barking, but is more like a clearing of the throat She goes out to walk daily

September 16 The cough has entirely ceased and patient can use her voice a little Her appetite and general health are improving

September 19 The voice is growing louder and clearer every day No return of the cough

September 29 Patient is able to talk in an ordinary tone without any hoarseness Her weight has increased several pounds Discharged well

In addition to the ice-bag, the following pill was given three times daily to stimulate the stomach

℞	Acid Arseniosi	gr 1 80
	Podophyli	1 20
	Quin Sulph	j
	Strychnine Sulph	1 80

and the patient also took one teaspoonful of malt after each meal Considering the large doses of strychnine and quinine which the woman had previously taken without avail, her improvement at the hospital would seem to be largely due to the influence of the spinal ice-bag

---

A CASE OF OVARIOTOMY

BY P J MURPHY, M D ,

OF WASHINGTON D C

To chronicle a success now a days in ovariotomy is, like "carrying coals to Newcastle," a work of supererogation, and I should not bring this to the notice of the profession, did I not deem it expedient to point out some minor details deserving more than a passing notice

The patient, Mrs D , aged 50, white, multipara, was first seen by me on the 5th of November last, when the following history was obtained There had been a gradual enlargement of the abdomen for three years, during which time she had been treated for an enlarged spleen, thought to be caused by chronic, malarial poisoning Accompanying the abdominal enlargement there had been anorexia, emaciation and progressive asthenia Of late, marked dyspnœa was experienced whenever the recumbent posture was assumed Urine normal Menstruation had ceased five years ago Upon examination, the abdomen was found to be enormously distended by an elastic, fluctuating mass Its contour was symmetrical and presented a slight appearance of flattening in the hypochondriac regions Flatness on percussion was everywhere present, extending even into the flanks The uterus was slightly increased in size, and seemed to occupy a position behind the tumor

The history of the case, together with its physical signs, clearly indicated that we had to do with a cystic tumor of the abdomen, which took its origin from the uterus, ovary, or broad ligament As a distinction between the last two conditions is unimportant as regards treatment, the problem presented for solution was, the possibility of excluding the presence of a fibro cyst of the uterus To accomplish this, is by no means easy In this connection Koeberlé states that "the diagnosis of fibro cystic tumors has, up to the present, been declared impossible by almost every author," and, as between uterine and ovarian cysts, Baker Brown admits that he knows of "no distinguishing marks" Later writers, however, take a more hopeful view of the situation, as the following table of differential points will illustrate

	OVARIAN CYSTS	FIBRO CYST OF UTERUS
Age	During period of ovarian activity 18-45 years	Generally *after* 30
Race	*Very rare* in negroes	*Most frequent* in negroes
Marriage	No influence	Generally in the unmarried or sterile
Duration	Relatively short Patient seeks advice early	Relatively long
General health	Not impaired at first Later emaciation urinary disorders hectic and prostration	Disease often present for many years without constitutional disorders
Menstruation	Normal or *absent* (both ovaries)	Normal or *profuse*
First noticed	In ovarian region	Above pubes
Examination Abdomen	Uniformly enlarged	Same
	Rotundity remains when recumbent posture is assumed by patient	Same
	Elastic and fluctuating	Increased sense of resistance Fluctuation often obscure
	Nodules when present *indistinctly* felt. (Endogenous cysts)	Nodules frequently felt low down *distinct, hard*
Uterus	Not connected with tumor normal in size retroverted *behind* tumor	Connected with tumor *Enlarged* drawn upward in pelvis
Fluid (most important in differential diagnosis)	Thick colloid sticky may be opaque opaline! Contains albumen *Not spontaneously coagulable*	Thick syrupy straw colored Contains much fibrin *Coagulates spontaneously*
Microscope	Drysdale's granular cell (Clears up upon the addition of acetic acid)	Fibre cells! No cells corresponding to Drysdale's

Although a careful review of the symptoms presented in this case suggested the probability of its ovarian origin, in my opinion a positive diagnosis, without the aid which a careful examination of the fluid would afford, was impossible, I therefore determined to perform *paracentesis abdominis* to secure a specimen of the fluid

And here let me call attention to the fact that the tendency of the day is to abandon tapping and substitute therefore, an exploratory incision I think this tendency is likely to be checked at no distant day, and it is my belief that were statistics furnished of the mortality following exploratory incision, it would be demonstrated that the operation is by no means devoid of danger Much can be learned by tapping without recourse to the more dangerous procedure of incision The removal of the growth should not, however, be delayed sufficiently long after tapping, to permit the formation of adhesions It may be urged that, by the employment of modern antiseptics, few cases terminate fatally as a result of exploratory incision Grant it! But the principle here as elsewhere should be observed, that of two evils, the *lesser* should always be chosen

A medium sized trocar was employed to obtain a specimen of the fluid, which was too thick to be withdrawn by means of an aspirator The wound was sealed with iodoform collodion, and the fluid sent to a competent microscopist for examination He pronounced the specimen as characteristic of ovarian dropsy containing numerous large, granular cells, corresponding in appearance and reaction to those described by Drysdale

During the night following the tapping, the patient was awakened from a sound sleep, with the feeling that "water was running from her stomach" Calling her daughter, it was discovered that from the puncture a steady stream of fluid was emerging A large slop jar was procured and the patient, turning upon her right side, filled the jar to overflowing The amount of fluid collected measured six and one half gallons I was summoned to see my patient, and after explaining the circuumstances, made an appointment to operate the following day

Assisted by Drs Wm Lee, Handy and Poole, Dr Brewer giving the anæsthetic, the usual operation was performed, lasting twenty eight minutes A large, partially collapsed, multilocular cyst of the right ovary was removed A quantity of the fluid contents of the sac was found in the abdominal cavity This was in part removed by means of hot carbolized sponges, although no effort was made to procure its *entire* removal The wound was closed by means of braided silk sutures which had been rendered thoroughly aseptic Iodoform gauze and marine lint constituted the dressing The patient sat up on the fourteenth day after the operation

The necessity of devoting scrupulous attention to the "toilet of the peritoneum," has been urged by most operators It seems to the writer that, in a great many instances, quite a number of extra frills are appended, which are not only needless but positively harmful If we consider for a moment what the peritoneum is, and what its function is, it will not require much knowledge to determine what amount of friction it will bear While "cleanliness is next to godliness," the too frequent use of the sponge in ovariotomy is often attended with danger

One other point *en passant*, the fluid contents of an ovarian cyst is, I believe, for the most part entirely innocuous That such was the case in this instance, is evidenced by the fact that a large quantity of the fluid remained within the peritoneal cavity for upwards of thirty six hours before the operation, without producing the slightest trace of irritation The record, also, of a large number of recoveries following rupture of the cyst, will tend to confirm this view

MEDICAL PROGRESS

Amputation at the Knee-Joint by Disarticulation, with Remarks on Amputation of the Leg by Lateral Flaps —At the meeting of the Royal Medical and Chirurgical Society, on December 8, Mr Thomas Bryant read a paper on this subject, which he commenced by saying that the operation of removal of the leg by disarticulation at the knee-joint was first practised in England by Mr S Lane, and had been advocated by Messrs G D Pollock, Pick, Stephen Smith, Markoe, Brinton, Staples, and himself It was still regarded with some suspicion and not frequently resorted to, amputation througn (or just above) the condyles being generally preferred The operation by disarticulation required for its success that the disease or injury should be confined to the leg, the condyles of the femur uninvolved or very slightly affected, and a sufficiency of healthy soft parts below the knee for the formation of a good flap If these conditions were not present, some other method of amputation would have to be adopted The author gave tables of his thirty cases, with the results Where there was no sloughing, no trouble was experienced with the articular cartilage on the condyles of the femur, and after healing the soft parts moved freely over the end of the femur The cicatrix was always placed well behind the femur The patella was preserved, its removal being found to be quite unnecessary The steps of the operation, after three different methods, were then described, viz that of Pollock by the long anterior flap, Pick's plan by lateral flaps, and Stephen Smith's method by lateral hooded flaps, and illustrations of the steps of the latter operation were shown The author endorsed completely the remarks of the American surgeon upon the value of this method of procedure, and strongly urged its application to cases of amputation in the leg also The muscle substance was generally included in the flap in thin subjects, but not in others The resulting stumps in the leg thereby obtained were excellent The method of Stephen Smith for amputation at the knee joint was to be preferred to either of the two other plans already mentioned, as it gave a better covering to the condyles of the femur, and the flaps were less prone to slough than in the long anterior flap of Pollock One case in five of the former sloughed, and rather more than half of the latter class of cases Smith's method also placed the cicatrix entirely behind the condyles and out of harm's way, whereas by Pick's method the cicatrix came to lie in the intercondyloid notch Moreover, Smith's plan permitted no bagging of fluids, the stump being in the best position for drainage The author advocated the leaving of the semilunar cartilages *in situ*, as of great advantage to the case, the soft parts being thereby all held well in place and the fascial relations preserved Dr Brinton, as early as 1872, had advised this point of practice Finally, the author summarized the advantages of this form of operation over amputation through the thigh in the following words (1) The lessened shock of operation (2) The lessened section of tissues and the non exposure of the muscular interspaces of the thigh (3) The escape from the necessity of sawing the femur, with its attendant risks (4) The preservation of the attachments of the thigh muscles, and consequently the greater mobility of the stump (5) The useful character of the resulting stump

MR PICK was glad that the subject had been brought forward, for he felt that the operation was still unpopular, and that preference was given to cutting through the femur, with its attendant dangers He preferred lateral flaps, in his earlier operations he had made long anterior flaps, and sloughing had frequently resulted, on one occasion he had practised a long posterior flap, but had found that it dragged upon the incision during repair The making of lateral flaps was, so to speak, an accident, they were necessitated by the condition of the skin in a traumatic case He rather disagreed as to leaving the patella, he thought that it was liable to be displaced, and that it might interfere with the fitting of an artificial limb

MR MARSH commented on the leaving of the articular cartilage, it was not only not followed by any untoward results, but it seemed to act in some measure as a barrier against absorption of wound products He did not think that any strong prejudice against this operation existed at St Bartholomew's It was very important to cut the flaps long enough

DR HARDIE (Manchester) spoke in favor of the operation He had read a paper at the Liverpool meeting of the British Medical Association, advocating its utility, but he preferred what he there called the "oblique circular" method He said there was no other stump, except that of a Syme's operation, which could compare with it, the anatomical conditions being just those favorable for a good result He thought the circular method lessened the chance of sloughing, as the skin flap remained a single piece He left the patella, and had never seen harm follow He was favorably struck with the idea of leaving the semilunar cartilage, it was of course a matter of great moment to secure, if possible, primary union

MR POLLOCK referred to the question of leaving the patella, there were decided advantages, less dissection was needed and few muscular insertions, he had never seen inconvenience result, not even as regarded the fixing of artificial limbs, on the contrary, the patients walked firmer, and with less throwing of the limb He preferred Dr Hardie's flaps to the lateral one advocated by Mr Pick

MR TIMOTHY HOLMES agreed that the results were very excellent when an operation was successfully carried out, but the method was more dangerous, and less often successful than amputations of the thigh done in any one way Such flaps, wherever and however obtained, were chiefly skin, and there was danger of their sloughing He approved of leaving the patella The danger of leaving a surface covered with cartilage was antiquated and exaggerated Nevertheless, the operation was one to be done sparingly and only after very mature consideration The plan of leaving the semilunar cartilages was a great improvement on the old plan —*Med Times and Gazette*, Dec 12, 1885

FRACTURE OF THE OLECRANON — In an original article on the prognosis and treatment of simple transverse fracture of the olecranon (*Centralbl für Chirurgie*, No 33, 1885), DR CARL LAUENSTEIN, of Hamburg, states that, in the opinion of all surgical authorities, union after this injury very rarely takes place by bone, but usually by fibrous bands which, according to their length, interfere more or less with the full use of the upper limb Hueter and Lossen hold that the chief cause of this failure of osseous union is the defective production of callus by the periosteum of the olecranon, which consists mainly of the non-vascular insertion of the tendon of the triceps According to Bardeleben, on the other hand, the formation of callus is prevented simply by separation during treatment of the two broken surfaces of bone Lauenstein agrees in the latter view, and asks why, if the periosteum of the olecranon is capable of producing callus in longitudinal fracture, it cannot do so when the fracture is transverse He holds that the prognosis of transverse fracture of the olecranon, and the probability of union merely by fibrous tissue, depend less on the special nature of the fracture than on inefficiency of such plan of treatment as is usually employed A treatment is advocated, which is analogous to that of Volkmann in dealing with simple transverse fracture of the patella The extra-articular collection of effused blood is first withdrawn by puncture, and the fragments are then brought into close apposition The three essential points in the treatment of transverse fracture of the olecranon are, it is stated, early removal of effused blood from the joint, prevention of separation of the fragments, and prevention of subsequent ankylosis of the elbow Such indications are not fulfilled by the ordinary plan of treatment It is clear that where, after an interval of from eight to fourteen days, the effusion of blood has been removed or much diminished by rest, elevation of the limb, cold applications, compression, etc , the chances of obtaining osseous union of the fragments have been lost The triceps muscle, deprived, through fracture of the olecranon, of its insertion, acts like any other muscle divided either by injury or in tenotomy, and undergoes more or less contraction When the effused blood is left to be removed by absorption, the risks of ankylosis of the elbow are considerably increased In most handbooks, the surgeon is advised to commence passive movement of the elbow about three weeks after the date of injury, an interval which is not sufficient for the attainment of complete osseous union of the fragments Simple extension of the forearm and forcing of the limb in this position do not suffice to keep the fragments in contact The author, after early removal of the effused blood, maintains the olecranon in contact with the ulna by applying strips of plaster wound diagonally around the arm, in order to avoid too much constriction Extension of the forearm is kept up for five or six weeks, until complete bony union has been established

THE VALUE OF CHLORIDE OF CALCIUM —In *The Practitioner*, Sept 1885, p 161, DR R W CRIGHTON contributes a most interesting article on the therapeutic value of chloride of calcium This drug is by no means a new one, but was well known during the last century under the name of muriate of lime

The author has used chloride of calcium for some years past, and says he knows of no other therapeutic agent that will produce the same good results in suitable cases In cases of glandular enlargements of the neck in children, it seems to have a wonderful effect, in many cases it must be given for a long time before any appreciable benefit is derived, and its use must be renewed at intervals to prevent a recurrence of the affection In pulmonary phthisis, it is useful only when there is evidence of the bronchial glands being affected, but in tabes mesenterica the good effects are striking and lasting, if the disease be not too far advanced In scrofulous caries it is also of great service Speaking of the physiological action of the drug, it is stated that its value is due to the activity of the chlorine, and to the especial function of lime in the assimilative and nutritive process Chloride of calcium is one of the normal ingredients of the blood, and is present in the gastric juice

In the *Brit Med Jour* , April, 1885, Dr Sidney Ringer records some experiments which throw light on the action of this drug If the heart of a frog has been subjected to the action of fluids, such as water or a solution of common salt, the ventricular contractions gradually cease and the ventricle stops in diastole The only constituent which will restore the suspended contractility is lime, by adding one part of chloride of calcium to 10,000 parts of saline solution, spontaneous contractions return, and the ventricle soon begins to beat as strongly as ever Any potassium salt has just the opposite effect The author always prescribes the crystallised chloride of calcium, as the anhydrous salt forms a turbid solution and has an unpleasant taste The dose given varies from 10 to 20 grains, but the author gives 1 to 3 grains for young children, and rarely over 12 to 15 grains for an adult

[Dr Coghill recommends 5 ounces of the crystallised salt in 12 ounces of syrup The dose of this solution varies from 5 to 40 minutes, three times a day It is best given in milk after meals A reference to the *Medical Digest*, sect 275 2, shows that this salt has been much appreciated in the past —*Rep*]—*London Medical Record*, Dec 15, 1885

LOCAL ANÆSTHESIA BY SUBCUTANEOUS INJECTIONS OF COCAINE —DR A LANDERER, of Leipzig, has recently made trial of subcutaneous injections of cocaine for producing local anæsthesia, and reports that the agent thus administered acts far better than anæsthetic ether, morphine, or any other means hitherto used with this object The mode of administration is very simple By means of an ordinary morphine syringe about fifteen minims of a four per cent solution are injected under the skin Anæsthesia is usually established at the end of five minutes If the patient after this interval still feel when the surface is scratched with a knife, the author waits one or two minutes longer The anæsthetic region is of about the size of a crown-piece A dissection, it is stated, may in this region be carried down below the fascia, and into the superficial layer of muscle, without causing any pain The influence of the cocaine is maintained for about half-an-hour If it be necessary to prolong the anæsthesia, a few drops of the solution may be applied to the wound, and allowed to remain until it is absorbed The subsequent healing of the wound is not in any way affected by the injection No unpleasant general after-effects have ever been observed by Dr Landerer, nor any local mischief, such as suppuration Injection of cocaine has been applied in cases of simple incision, of needle-extraction, and of removal of small tumors It has been applied also in a case of hydrocele Fifteen minims of a four per cent solution were first injected into the sac, and five minutes later, through the same canula, about a drachm and a half of a solution of iodine The latter injection did not cause any pain About six hours after the operation the patient complained of slight and very transient uneasiness Cocaine injection as a means of producing local anæsthesia is far preferable, Dr Landerer asserts, to the ether spray The cocaine solution, when introduced through a fine and and sharp needle, does not cause so much pain as the ether does, whilst freezing the skin The anæsthetic influence of the ether spray does not extend below the skin After injection of cocaine, on the other hand, the parts immediately below the skin are quite free from pain and sensation —*London Medical Record*, Dec 15, 1885

Treatment of Catarrhal Phthisis, of Hæmoptysis, and of Chronic Bronchitis by Terpene —Professor Germain See gives the following *resume* of his paper on this subject

1 It diminishes and quickly arrests purulent expectoration in catarrhal forms of phthisis Whether the muco purulent secretions proceed from the bronchi, irritated by tubercles, or from the walls of pulmonary cavities, whether the malady is at an early stage, or at a phase of purulent breaking down, or even of cavities already formed, terpene should be used whenever the formation of pus is sufficiently abundant to tire the patient, to exhaust the strength, or to cause him to waste away

2 It should be used with success in the hæmoptysis of the early stages of tuberculosis, that is to say, when the disease has not yet developed large cavities, with aneurisms of the pulmonary arteries

3 In the treatment of pulmonary catarrhs, of chronic bronchitis not dependent on asthma, and only producing dyspnœa by choking the bronchi, terpene constitutes the best method of lessening bronchial hypersecretion

4 The action is quick, sure, and free from physiological inconveniences, rendering it preferable to preparations of syrups of turpentine or tar, or of shoots of pine, which contain so little of it, and to essence of turpentine, which is not tolerated It even offers advantages over creosote, on account of its perfect innocuity and easy digestion

5 The best way of administering this medicine is either in the form of pills or tincture, and the best dose is one gramme

6 In catarrhal, or emphysematous, or nervous asthma, which is to be distinguished from primary catarrh, iodine and pyridine have an incontestable superiority —*Bulletin de l' Academie de Medicine*, No 30, 1885

Cocaine for Allaying Pain in the Destruction of Cancerous Growths —In the *Lancet*, Oct, 1885, p 663, Mr C E Jennings records two cases in which he used cocaine to alleviate pain, whilst caustics were applied to cancerous growths One patient was aged 73, and suffered from extensive scirrhous ulceration of the right breast The surface of the ulcer was covered with rugged irregular granulations which bled upon pressure, the veins around the growth were much engorged, and the pain was increasing After painting the ulcerated surface with a ten per cent solution of hydrochlorate of cocaine, a paste was applied consisting of cocaine, potassa fusa, and vaseline After some minutes a burning sensation was experienced, then the paste was quickly removed with the charred tissue, by means of pledgets of cotton-wool previously moistened with water The denuded surface was again painted with cocaine solution, and the compound paste reapplied By this means, more than a tablespoonful of cancerous growth was removed by a rapid and painless process The next day a clean, smooth, and bloodless surface, insensitive to the touch, was presented By this means, most of the scirrhous mass was removed after a few applications In the second case, the author destroyed a cancerous growth of the os and cervix uteri, by means of sticks of potassa fusa, and a ten per cent solution of cocaine —*London Medical Record*, Dec 15, 1885

Anæsthesia by Chloroform and Oxygen —At a meeting of the St Petersburg Medical Society, Dr Berteis (*Vratch*, No 48, 1884, p 816) made a communication on artificial anæsthesia after Neudorfer's method somewhat modified by himself Anæsthesia by means of a mixture of chloroform with oxygen requires far less quantities of chloroform comparatively with the usual methods of its administration, and is, correspondingly, associated with lesser danger Moreover, perfect anæsthesia ensues far more easily, and may be obtained even in those patients in whom chloroform alone has failed When the quantity of chloroform in the mixture does not exceed 10 per cent, no sickness is observed The pulse remains unchanged, the tongue never falls back To ensure complete narcosis, it is essential to firmly adjust the mask to the patient's face Professors A J Krassowski and V V Sutugin have also obtained good results from the use of a mixture of chloroform with oxygen —*London Medical Record*, Dec 15, 1885

A New Use of Atropine —Dr Frederic C Coley writes to the *British Medical Journal*, of Dec 26, 1885, as follows We often find it necessary to advise patients not to read, or write, or do any work requiring close attention In many cases, the patients are equally ready to promise obedience, and to break the promise under slight temptation Under these circumstances, we may fairly make the necessity for careful ophthalmoscopic examination (always desirable in these cases) an excuse for crippling the power of accommodation by a tolerably strong solution of atropine, the instillation to be repeated as often as necessary I generally use homatropine to dilate the pupil for merely diagnostic purposes, because the effect of it passes off in a few hours But in such cases as I have alluded to, atropine is preferable Of course, this suggestion is obvious enough, but it may be none the less useful for that

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.
PER ANNUM, IN ADVANCE $5 00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

SATURDAY, JANUARY 16, 1886.

THE TREATMENT OF CHRONIC HEART DISEASE BY MEANS OF BATHS AND GYMNASTIC EXERCISE.

Every practitioner, who has much to do with the treatment of heart-disease, must eventually come to appreciate that internal remedies have their limitations, and to long for some other effective means of reinvigorating damaged hearts. Digitalis has been the sheet-anchor in such cases, supplemented by rest and tonics. Most gratifying results have often rewarded the judicious physician. Perhaps as often his efforts have been frustrated by indiscretions on the part of the patient, or intolerance of medication. Therefore, although the prognosis as to speedy death may be favorable, the hope of ultimate recovery has to be abandoned. Such at least has been the opinion, either tacit or expressed, until within the last few years. In Germany, the treatment of chronic heart-disease has taken a new departure since the publication of Oertel's "Method of Therapeutics," the principle of which consists in the reduction of bodily fat and water. This is accomplished by diet, baths and mountain climbing (see editorial in THE JOURNAL, Vol. V, No. 17.)

In the same line as Oertel's in principle, yet differing from it in method, is the treatment employed by DR. AUGUST SCHOTT, physician of the baths of Bad Nauheim, Germany. His system is set forth in the *Berliner Klinische Wochenschrift* Nos. 33, 34, 35, 36, 1885. The principle of the treatment is to further the nutrition of the cardiac muscle, and thereby obtain an increase in its bulk, or, in other words, to promote hypertrophy and lessen dilatation. In this there is nothing new or original. It is only the means for obtaining this object which is novel. Notwithstanding the announcement of Beneke, in 1872 that sufferers from rheumatism, complicated by disease of the heart, were often greatly benefited by a judicious course of baths, that, indeed, as he expressed it, "even fresh endocarditic vegetations may often be absorbed," notwithstanding this statement as the result of Beneke's observation so long ago, and in spite of Oertel's publication, Schott claims priority in the recognition and advocacy of baths and exercise as therapeutic agents of the greatest value in diseases of the heart. He began his observations, he says, in 1871, but was unable to publish the results until 1883. At that date his brother, Dr. Theodore Schott, who has been his assistant, published the account of a single case which had experienced marked benefit from several systematic courses of baths, but was unable to employ the advantageous auxiliary of exercise.

Schott does not think it always necessary or judicious to reduce the fat and liquids of the body, to the same extent as Oertel. Nor does he believe in the employment of mountain climbing at the commencement. He would only have the patients resort to it after having prepared themselves for it by such gymnastic exercises as he describes. Schott asserts that, under his method of treatment, he has frequently recognized marked decrease in the area of præcordial dulness, an increased vigor of the pulse, and the disappearance of symptoms dependent upon venous engorgement. Altogether he has had 300 cases of heart-disease under his care since 1871, but as most of them returned to their homes before the benefit derived had become permanent, he has had to depend for his knowledge of their subsequent condition upon the reports of their family physicians. These have been for the most part highly gratifying. He disclaims any intention of advertising the baths at his resort as alone beneficial in such complaints. Favorable reports have been made by Mayer, of Aachen, Groedel, of Nauheim, and by Scholz, of Cudowa. Schott regards as particularly interesting the reports from the baths of the last named resort since their waters are chalybeate. Results from the employment of these waters exclusively are gratifying, but in his opinion they are not as great and enduring as from carefully graduated baths of warm alkaline waters, supplemented finally by such as are rich in carbonic acid. With these preliminary remarks we pass to the consideration of Schott's method of employing baths.

The scientific administration of mineral waters according to pathological process in each case is most desirable, but as yet Schott thinks it is seldom done. With but a few exceptions the literature of Balneo therapeutics is stuff and nonsense. Baths are prescribed in accordance with general indications instead of the peculiarities of each individual disease. System is necessary to the achievement of the best results. He therefore presents his method of employing baths, since its worth is attested by fourteen years of experience. Accordingly, patients whose diseased hearts are in the stage of ruptured compensation, should begin with diluted baths free from gas. It is not of interest to know which of the springs in Bad Nauheim are first used, and hence we shall give only his directions for the preparation of artificial baths. To this end he recommends the addition of one to one and a half parts of common table salt, and chlorate of lime to every one thousand of water. The bath at first should not exceed ten minutes, and for delicate persons not five. If the individual be rheumatic, or anæmic, or be specially sensitive to cold, the temperature of the bath should be 86° F., since, if the heart's vigor be below par, the circulation is not brisk enough to react well against any chilling of the surface of the body. Care should be taken to have this temperature maintained, since a difference of 2° less may produce an injurious chill in an individual with a weak pulse, an already cool skin and impaired nutrition. If the blood be driven in too large quantities into the interior, the resistance to be overcome by the weakened heart is augmented, and the cardiac disturbance is increased. The pulse becomes more rapid, smaller and more irregular, and dyspnœa greater.

If the patient be of a rheumatic diathesis, he must wait longer than others before trying cooler baths, since there exists a tendency to fluxions to the seats of former attacks and this must be guarded against. A higher temperature than 86° or possibly 88° F. ought never to be allowed, since the effect of the bath is lost, while, on the other hand, this degree of heat proves derivative, lessening congestion of internal organs and promoting free perspiration. The patient should be instructed to lie motionless for the *first half minute, until he feels perfectly comfortable*. If reaction does not set in at the end of that time, the temperature of the bath must be increased. Special care must be had that the patient does not remain long enough in the water to have the reaction succeeded by a feeling of chilliness. In such an event he must recover his warmth by rapidly raising the temperature of the bath, and then leave the water so soon as that is effected. The next bath must then be warmer and of shorter duration. As the patient becomes accustomed to the temperature prescribed and his circulation and nutrition improve, he may take gradually cooler and cooler baths. The difference should not exceed 1° F. at a time, great care being exercised to guard against a chill.

It is advisable to intermit a day in the baths, either after the first or the second one. They may then be taken daily, with the exception of one day in the week. As the strength of the heart increases, thus allowing a gradual lowering of the temperature, the length of stay in the water and the strength of the salts in solution can be increased. The former should not exceed twenty minutes, while the latter may be made to reach the strength of the waters of Bad Nauheim. Finally the patient is able to endure a water impregnated with carbonic acid. The effect of each bath upon both the heart and the whole organism must be the guide to any increase in length or strength of the bath. If the feeling of fatigue last an hour or two, the next day's bath should not be in anywise strengthened. The baths have been followed by complete results only when immediately afterward the pulse is found to be slower and by the sphygmomanometer stronger than before. A perceptible diminution in the size of the pulse should also be demonstrable, although it may return to its former dimensions during the day. A further consideration of the subject will be found in our next issue.

THE TREATMENT OF RUPTURED LIGAMENTUM PATELLÆ

Of the many valuable papers read before the New York Surgical Society during the past year, none were more interesting than one on "Rupture of the Ligamentum Patellæ, and its Treatment by Operation," read on December 8, by Professor Henry B. Sands. The comparative infrequency of rupture of this tendon as compared with fracture of the patella—about one to twenty-five, as gathered from the records of the New York, Bellevue, Roosevelt, and St. Luke's Hospitals—need not detract from the interest of the accident, and certainly does not diminish the importance of skilful treatment when it occurs. The rarity of the accident is probably to be ascribed to its great strength and thickness, "its relatively slight exposure to direct injury, and to the great mechanical advantage with which indirect violence often acts in causing fracture of the patella."

The first case (personal) recorded by Dr. Sands was that of a man who had had a fracture of the right patella ten years previously. Five months later it was again fractured, the result being fibrous union between the fragments, at a distance of two inches. The accident for which he was admitted to the hospital in 1882, when Dr. Sands first saw him, was a complete rupture of the ligamentum patellæ, close to its inferior extremity. The limb was extended to a horizontal position, and ice applied to the knee. On the ninth day, the pain and swelling having subsided the limb was suspended vertically, and a rubber bandage applied. About five weeks afterwards a water-glass bandage was applied from the ankle to the thigh, and the patient allowed to walk, and he was discharged on the fourth day after this, wearing a splint. He was examined in November, 1885, three years after the injury. Having disobeyed instructions, after leaving the hospital, by removing the splint and using the limb more freely, his knee remained stiff for five weeks, when mobility was suddenly restored by what must be regarded as a rather fortunate strain. Examination showed that the ligaments were equally long on both sides, and one leg seemed to be as strong as the other.

The second case recorded in the paper was treated by operation. The ligament, as nearly as could be ascertained, had been ruptured close to its inferior attachment, the accident having occurred at sea eight months before he came under the care of Dr. Sands. Three months after the accident the joint was incised to let out a collection of fluid, but no attempt was made to repair the injury. A longitudinal incision, six inches long, was made in the median line on the anterior aspect of the knee, with the centre of the incision opposite the lower edge of the patella. It was subsequently found necessary to lengthen the incision to nine inches. "On exposing the injured parts, in doing which the joint was freely opened, it was found that the ligamentum patellæ was torn away from the spine of the tibia," which was covered by a small amount of fibrous tissue, but enough to afford a hold for sutures. A little more than one inch of the ligament, in good condition, was attached to the patella. There was no union between the severed ends of the ligament, and it was with difficulty that they were brought together after being fastened. It was necessary to make deep oblique and transverse incisions in the quadriceps tendon before the upper end could be sufficiently drawn down to be connected with the lower, and it being evident that considerable force was necessary to secure and maintain apposition, two strong silver sutures were used, the ends twisted, "cut short, bent flatwise, and buried in the wound. The mucous and alar ligaments were found redundant, and were partly removed with the curved scissors. The incisions in the capsule of the joint were closed by catgut sutures," and the external wound united in the same manner, except at the upper and lower ends. A bone drain was placed in each extremity of the median incision, and one on each side, in openings made for the purpose. The antiseptic used was a 1 : 1000 solution of corrosive sublimate, and the wound afterwards covered with iodoform gauze. The limb was then enveloped in a moss-bag, moistened with bichloride solution, and fastened to a long, straight wooden splint, to which a foot piece was attached. Two months afterwards, when the patient was allowed to get up, a leather splint was applied, which was used two or three months, and then laid aside.

The final result in this case has been most satisfactory as regards usefulness and mobility, and this and the impunity with which the knee-joint can be opened, and even somewhat roughly handled, *with strict antiseptic precautions*, certainly seem to warrant opening of the joint in such cases. Success or failure in these cases seem to depend entirely on the proper observance of antiseptic principles, and we need not cite other operators than Dr. Sands to show that the most formidable operations can be done on the knee joint with a relative and absolute minimum of risk by following out the Listerian principles. Even the student of a few years ago can remember the reluctancy with which the peritoneal cavity was opened, and to day few operators hesitate to open it for exploratory purposes. We must heartily endorse the opinion expressed by Dr. Sands when he says that it is reasonably safe, "and I cannot doubt that the operation for opening the knee joint is already, when properly performed, far safer. I confidently anticipate the time when skilful and careful surgeons will be able to divest it of all danger either to life or limb, and, whenever this time arrives, our time honored, but clumsy, tedious and uncertain method of treating both fracture of the patella and rupture of its ligamentous attachments may well be abandoned in favor of sone form of operation calculated to secure an immediate union of the divided parts."

REPORTING CASES OF INFECTIOUS DISEASE.

There is no part of a physician's duties that requires more careful attention and strict accuracy of judgment, than in the diagnosis of such infectious diseases as he is required to report to the health authorities of our towns and cities. And it would appear from some recent judicial decisions that no part of his duties involves more danger both to his own reputation and his pecuniary interests. To report a child having only a catarrhal sore throat as a case of specific diphtheria is equivalent, in many cases, to shutting all the rest of the children of the family out of school for two or three weeks, and keeping the whole family in semi quarantine. Yet this is a very frequent mistake, with one class of practitioners at least. A less frequent mistake, but one which we have known to occur several times, is the calling of a simple evanescent fever accompanied by a fine miliary rash, scarlet fever. But the most serious of all this class of errors consists in pronouncing a case to be varioloid or small pox, which is only varicella, measles, or perhaps a few pimples of acne accidentally accompanied by fever of a transient character. It is more serious because it generally involves the removal of the patient to the pest-house or small-pox hospital, where he will be certain to be exposed to the contagium of that disease if he is not already laboring under it. No less than three cases have come under our own observation in this city, in which measles had been pronounced small-pox by the attending physician, and were prevented from a journey to the small-pox hospital only by a timely correction of the diagnosis. And it is not many years since a patient affected with measles was pronounced by the Medical Examiner of the Health Department to be laboring under small-pox and was removed to the pest house, where she soon recovered from the measles, but in due time was actually attacked with small-pox contracted in the hospital to which she had been taken by the health authorities.

A large proportion of such errors are caused either by carelessness in not obtaining a full history of the development of symptoms, or in an attempt to make a positive diagnosis before the disease has progressed far enough to enable the most skilful to render a reliable opinion. The practitioner often feels himself in a dilemma concerning such cases. If he hesitates or delays for more decided symptoms, and the case proves to be of an infectious or contagious character, he is liable to be censured for delay in reporting to the Health Department as well as by those who may be more or less in contact with the patient. If, to avoid this, he allows himself to make a hasty diagnosis, and, as some say, to be on "the safe side" pronounces it contagious and reports accordingly, he makes himself liable for all the damage that may follow to the person and business of the patient, if the resulting history proves his diagnosis to have been erroneous. Nothing could illustrate more fully the necessity of more attention to the clinical study of diagnosis as a part of the education of every medical student.

These thoughts have been suggested by a case recently brought in one of the courts of New York City. Dr. A. F. M. Purdy, a practitioner of experience and high standing reported a case to the Health Department as one of small pox. The Health Officer sent one of the medical examiners of that Department, who, after examining the case, confirmed Dr. Purdy's diagnosis, and the patient was removed, contrary to her own wishes, to a public hospital for contagious diseases. The sickness proved of short duration, and the patient brought suit against Dr. Purdy for damages on account of alleged erroneous report of her case to the Board of Health. The result was that the jury awarded the patient a judgment of five hundred dollars against Dr. Purdy, notwithstanding that both he and the medical examiner of the Health Board still claimed that their diagnosis was correct. It will thus be seen that in the matter of infectious and contagious diseases, the practitioner stands between two dangers. If he fails to report a case to the Health Department he is liable to prosecution and fines, and if he does report it and subsequent events throw the least doubt upon the correctness of such report, he is liable to prosecution by his patient, and heavy damages at the hands of a jury.

REGENERATION OF DIVIDED TENDONS.

The method which was applied by Gluck to the human subject has been recently studied anew by MM. FARGIN and ASSAKI on rabbits, the object being to ascertain the best method of causing regeneration of divided and shortened tendons. It will be remembered that Gluck joined the cut ends of a divided tendon by means of a bridge of catgut threads. Fargin and Assaki, having excised a portion of the tendo Achillis of a rabbit, filled the gap with catgut threads, strict antiseptic precautions being observed in order to ensure primary union. The animal being killed on the forty-ninth day, examination showed that the catgut threads were replaced by fibrous tissue, not identical in structure with tendon, but closely resembling it. Another animal operated upon in the same way was killed on the one hundredth day. The newly formed tendon was much more fully developed than in the first case, as was to be supposed.

The experimenters then substituted portions of tendon for the catgut, the tendons being taken indifferently from animals of the same and different species as the animal operated upon, portions of tendon from a sheep, a dog, chicken, and duck being used on rabbits, and *vice versâ*. The zoological relationship seemed to have no effect in promoting or detering union by first intention. Notwithstanding this, the experimenters assert that when primary union is impossible, and some substitute must be used for lost tendon substance, success will be more probable if the substitute be taken from an animal nearest to man in zoological order We do not see that this necessarily follows The results of these experiments are satisfactory, and are certainly sufficient warrant for the performance of the operation on man, of course under strict antiseptic measures

---

SMALL POX CHOLERA AND YELLOW FEVER

From the circular issued from the office of the National Board of Health, dated Dec 30, 1885, we learn that during November and December, cases of small pox continued to occur in Montreal and its vicinity, and two cases in Toronto In Europe cases of the same disease have been reported in London, Bradford, Bristol, Glasgow, Edinburgh, Paris, Bordeaux, Rheims, Antwerp, Zurich, Genoa, Leghorn, Venice, Prague, Trieste, Munich, St Petersburg and Warsaw Cases and deaths from cholera are reported as having occurred in Calcutta, in Osaka and Kioga, Japan, in Navarra and Zamora, Spain, in Finisterre, France, and in the Provinces of Palermo and Venetia, Italy Yellow fever is mentioned as existing at Havana and Caracas only

It will be seen that the contagium of small-pox is very widely diffused in Europe, and though steadily diminishing, is still destroying several lives each week in Montreal and its vicinity on this side of the Atlantic, while just enough of cholera lingers in Spain, Italy and France to keep the essential cause from becoming extinct during the winter, and to favor its increase and spread with the return of the next warm season

---

Death of Dr William Marsden—Dr William Marsden, of Quebec, Canada, recently died at his residence in that city in his 79th year He was one of the oldest and most eminent members of the profession in that country He had been an active sanitarian and had written much in reference to the etiology and modes of spread of epidemic cholera and the means for preventing the latter He was a firm believer in the contagiousness of the disease He was a visiting member of the American Medical Association at some of its annual meetings, and his name was on the Council of the Section of Public and International Hygiene of the Ninth International Medical Congress, at the time of his death

---

Correction—In stating, in issue of The Journal for January 9, that the *January* number of the *Chicago Medical Journal and Examiner* contained a full and connected history of the progress of the Organization of the Ninth International Medical Congress, we should have said the *December* number instead

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, December 3d, 1885

The President, B F Baer, M D, in the Chair.

(Concluded from page 50)

Dr Keating reported a case of

VESICO VAGINAL FISTULA,

from notes by Dr Howard H Pardee Rebecca Johnson, colored, married, was admitted to the Philadelphia Hospital in the summer of 1884, complaining of inability to retain her urine, and of a constant bearing down pain in the hypogastric region, a burning pain in the bladder, and of frequent back aches. She had noticed that the urine was sometimes blood-stained in the inter-menstrual periods She stated that about a year previously she had fallen out of bed and had struck upon a broken chair, one of the rounds of which had entered her vagina, hurting her severely, and that all her symptoms had dated from that accident Soon after her admission to the house an operation for vesico vaginal fistula was performed by Dr M B Musser, which relieved her for a time, but soon all the old symptoms returned In January, 1885, examination revealed an opening from the vagina into the bladder more than an inch and a half in length, involving the neck of the bladder and the posterior part of the urethra A pedunculated growth was also found in the bladder, and was removed No history of venereal disease could be obtained, there was a bad leucorrhœa In May, examination showed an enormous vesico-vaginal fistula, the neck of the bladder and the urethra had entirely disappeared The edges of the fistula were very thick and callous, and anteriorly very little tissue was left beneath the pelvic arch A small recto vaginal fistula was also found, and exhibited the same thick, rigid edges Several deep scars were found on the nymphæ and labia majora, which seemed to be the marks of healed chancroids An operation for the closure of the vesico vaginal fistula was performed Nov 15, 1885, but the patient died a week later. The specimens showing the wound closed were exhibited to the Society

Dr B F Baer presented the specimens and read the report of a case of

HYDRO- AND PYO SALPINX, COMPLICATED WITH FOLLICULAR DEGENERATION OF THE OVARIES

Mrs H, æt 42 years, was sent to me some months ago She complained of great pain in both iliac regions, more in the right, radiating into the pelvis and sacrum and down the limbs She had menorrhagia, and profuse leucorrhœa during the inter-menstrual periods She dated the trouble from an abortion which had occurred nine years before, and which was followed by symptoms of acute parametritis, from which she had never fully recovered Examination showed the uterus to be considerably hypertrophied, and fixed as in a vise by an indurated mass on either side of it, which seemed to occupy both broad ligaments, or to be closely adherent to them The cervix uteri was also badly lacerated, and its mucous membrane presented a surface so hypertrophied, abraded, and jagged, that I was at first strongly impressed with the fear that epitheliomatous degeneration had begun to develop I pursued a plan of treatment designed to reduce the congestion and hypertrophy of the diseased neck, and at the same time to induce an absorption of the plastic and indurated lymph around the uterus, to render the organ mobile, so that an operation might be made safe I only partially succeeded, for while the uterus became much more mobile, there still remained a swelling or tumor on either side of it These tumors had illy defined borders, were not circumscribed, but were elongated and rather cylindrical in form, and fixed to the lateral pelvic walls, as well as to the uterus, though not very firmly to either

I now suspected disease of the fallopian tubes, and probably also of the ovaries The patient entered my private Hospital in February, 1885, when I operated upon the cervix, dissecting away a large quantity of tissue for the purpose of making proper adjustment of the labia and to get rid of the cicatricial tissue It was not epitheliomatous I had *hoped by this operation not only to restore the cervix* to health, but at the same time to induce, by a derivative action, a retrograde metamorphosis in the diseased tissue and organs appended to the uterus I succeeded in the former, and also in modifying all of the symptoms except the pain in the ovarian regions This seemed to be made worse, or at least to become more prominent as the other symptoms were improved The patient was sent to her home, and advised to rest in the recumbent position for at least a part of every day Later, as she did not improve, a local treatment consisting of an application of the tincture of iodine to the fundus of the vagina at intervals of a week, with biroglyceride tampons almost daily At the same time counter-irritation applied to the iliac region by means of blistering was faithfully pursued Nothing proved of more than temporary benefit She began to lose flesh and fail in strength The fulness at the sides of the uterus had increased

She again entered my private hospital, and under anæsthesia I determined that the fallopian tubes were distended to the size of a small sausage, that the ovaries were also enlarged, and that the tubes, ovaries and ligaments were all adherent to one another by plastic lymph I advised laparotomy for the removal of the uterine appendages, the patient readily assented A week later I made an incision three inches in length through the abdominal wall—fully two inches in thickness—and came upon the omentum, which was also very fat This was adherent by its lower border to the pelvic tissues and organs, so that I was compelled to dissect it off on the right side before I could reach the uterus with my finger Everything, fallopian tubes, ovaries, broad ligaments, uterus, omentum and intestines were so adherent and matted together that it was difficult to differentiate between them The tubes were greatly distended and contained, the right, pus, and the left, serum The fimbriated extremities were glued to the lateral pelvic walls The ovaries were as large as a good-sized hen's egg, and were closely adherent to the posterior surface of the broad ligaments I dissected with my fingers, two being introduced until the right tube and ovary were released when they were drawn to the incision, ligated and removed The left tube and ovary were released with still greater difficulty, but I finally succeeded in ligating and removing them Considerable hæmorrhage occurred during the operation, and it was necessary to place a number of ligatures The abdominal wound was closed with eight silk sutures The operation occupied more than two hours The patient slept four hours before she returned to consciousness, and awoke without the slightest nausea, which both she and I dreaded very much from previous experience There is not much to say concerning the after treatment, for she did not require much Her temperature never rose above 100°, and she made an uninterrupted recovery She went home at the end of five weeks, and has been free from the old pain in the iliac region since four days after the operation

Dr B F Baer also exhibited

A SMALL FIBROUS TUMOR WHICH HAD UNDERGONE CALCAREOUS DEGENERATION

Mrs L , æt 60 years, of Lancaster Co , Pa , a patient of Dr J H Musser, has had two children and two miscarriages She had been treated for uterine hæmorrhage a number of times during the last fifteen years She continued to "menstruate" until she was fifty-seven years of age One year afterwards she began to suffer from severe uterine tenesmus, which was soon followed by a severe attack of "flooding" After this she had frequent recurrence of the hæmorrhages, up to the time of the removal of the cause The case had been looked upon as one of cancer, and had been abandoned to the fate which attends that dread disease, but she lingered on and finally came under the care of Dr Musser, who found on examination that the cervix at least was not cancerous Through his kindness I saw the lady at her home in September, 1885 I must confess that when I entered the room I was almost on the point of quietly saying to the doctor that I believed his patient had cancer She had a marked cachectic appearance, and there was an odor very like that of cancer I advised that a thorough investigation be made with the patient under ether *I found the cervix* smooth and soft, the os slightly patulous, and there were several mucous polypi hanging from it There was also a fœtid muco purulent discharge which seemed to come from the cavity of the uterus I removed the polypi and then carefully passed the sound into the uterine cavity, it was large and filled with numerous soft bodies, vegetations, except at one point at the fundus Here a mass was detected which was as hard as marble, and gritty I next dilated the cervix with my steel dilator—which was easily done because the tissues were so soft and dilatable—and passed my finger into the cavity The finger confirmed what the sound had led me to infer I now removed, with the dull curette, all of the fungous vegetation, enough to fill a large spoon in the aggregate, and then again introduced my finger and found that the hard mass was imbedded in the uterine wall and pedunculated I endeavored to remove it with my finger, and failed, I then pried it out of its nest with one blade of a polypus forceps It proved to be a fibroid tumor which had undergone calcareous degeneration I cauterized the entire surface of the uterine cavity with fuming nitric acid The patient has had no hæmorrhage since

This case is valuable scientifically because it shows the fallacy and danger of neglecting cases of metrorrhagia first, on the theory that the hæmorrhage is due to the change of life, and therefore physiological, and second, on the supposition that because the hæmorrhage came on so late in life it must necessarily be the result of malignant disease and be permitted to run its course unmolested Untold suffering and loss of life has resulted from this want of action I have so recently expressed my views on this subject in a paper on "The Significance of Metrorrhagia recurring about and after the Menopause," *Am Jour Obstetrics*, May, 1884, that I refrain from further comment here

Dr Parvin, remarked that the last case reported by Dr Baer illustrates the importance of a careful local examination in severe uterine hæmorrhage, since in almost all cases such hæmorrhage is sympathetic

Hippocrates was probably the first to observe the discharge of stones from the vagina He mentions a Thessalian servant who twice passed from the uterus what would now be regarded as uterine fibroids which had undergone calcareous degeneration I have seen in one case in a post-mortem examination between thirty and forty calcified uterine fibroids

Quite recently there came to my knowledge through a medical friend, the history of a case which very strikingly illustrates the difficulty of arriving at a correct diagnosis in severe ovarian, then uterine pain A married lady, about thirty-five years of age, and the mother of three or four children, was attacked with sharp pain in one of the ovaries, the pain occurred in violent paroxysms during several months, baffling alike the diagnosis and therapeutics of competent professional gentlemen, then suddenly ceased But while the ovary was relieved, equally severe suffering came in the uterus, it persisted several months, and only ceased with the discharge from the organ of a sewing needle

Dr Charles M Wilson could not understand how Dr Baer could make out his diagnosis in the case first described with two inches of fat in the abdominal wall, how could slightly enlarged ovaries and tubes glued down by lymph deposits be detected? He felt sure he could not do it himself

Dr Parrish said the diagnosis of such cases is at all times difficult, but the history of the case, with the aid of the examination, will make the examination almost certain, sufficiently so to warrant an exploratory incision Calcareous degeneration, in fibroid uterine tumors in old women, is frequently found in post-mortem examinations The calcareous mass may be as large as a child's head

Dr Baer, in closing the discussion, remarked that the great difficulty of making a diagnosis was an inducement to present the case before the Society He had been eight months in making the diagnosis, and finally operated with hesitation and many misgivings The pains were chiefly ovarian, but at first he contented himself with repairing the cervix and endeavoring to promote absorption of lymph deposits, and although there was improvement, the ovarian pain remained When the patient returned, the cylindrical mass on the left side was ten inches in diameter, and could be outlined per vaginum, the ovary was as large as a hen's egg This I could determine by examination under ether, and on the right side a hard tumor could be felt This proved to be the thick walled tube filled with pus, it was circumscribed and attached to the broad ligament I felt sure about the diagnosis, but the adhesions made me hesitate long before yielding to the desire of the patient for an operation

AMERICAN PUBLIC HEALTH ASSOCIATION

Thirteenth Annual Meeting, held at Washington, D C, December 8, 9 and 10, 1885

(Continued from page 48)

Thursday, December 10—Third Day

Evening Session

Dr S H Durgin, of Boston, submitted the report of the committee on

DISINFECTION AND INDIVIDUAL PROPHYLAXIS AGAINST INFECTIOUS DISEASES

The first prize for the essay on this subject was awarded to Dr George M Sternberg, U S A

The second prize for the essays on *The Preventable Causes of Disease, Injury and Death in American Manufactories and Work-Shops, and the Best Means and Appliances for Preventing and Avoiding Them*, was awarded to Dr Geo H Ireland, of Springfield, Mass

At the conclusion of the reports of the committees the President introduced Mr Henry Lomb, of Rochester, who, he said, out of his comparatively small means, had conferred an immense favor upon sixty million people

Dr J S Billings spoke in terms of great praise of Mr Lomb and the compliment he had offered this Association, and moved that Mr Lomb be invited to take a seat upon the platform, and that he be elected a life-member of the Association This was done by a unanimous rising vote

The President announced that Mr Lomb would continue the amount unappropriated by the Committee (which amounted to $1700) for another year, with such change in any of the titles of papers as the Executive Committee might decide upon

Dr D A Sargent, of Harvard University, as Chairman of the Committee, then read the

REPORT OF THE COMMITTEE ON SCHOOL HYGIENE

The uneven manner in which physical and mental training are distributed is shown at once by the fact that those schools which have large play grounds attached and a river on which to row boats, never fail to advertise that fact, while those not having such advantages give their attention to theoretical training As a consequence, there are dissatisfactory reports from all sides Here we have all muscle and no brain development, and the superior mental attainment with nervous prostration The committee thought that course of training should be universally adopted which actual observation had proved to most thoroughly distribute physical exercise in proper proportion with the mental exercises of education The youth should also be thoroughly taught the first laws of the body, the necessity of cleanliness pure air in houses, etc , and not only taught these principles but shown how to practically use their knowledge

DR JOHN MORRIS, of Baltimore, then presented

THE REPORT OF THE COMMITTEE ON DISPOSAL OF THE DEAD

This subject has attracted much attention and been thoroughly discussed No doubt the general acceptance of the germ theory and the surprising discoveries of Darwin and Pasteur concerning the life and office of ground worms have materially influenced public thought in this matter Even those who do not favor cremation admit the necessity of reform in the present mode of burial Cremation is gaining ground in Europe A bill legalizing the process has been introduced in the French Chamber of Deputies, and is supported by such advanced thinkers as Paul Bert and Tony Renelon It is proposed to build a large crematory near Paris, and an engineer has been sent to Italy to study the best plans Three hundred and ninety-six bodies were cremated in Italy during the past year

A valuable contribution to the subject of inhumation has been recently made by two French writers The deductions therefrom are that in every cavity dug where organic matters are decomposing there are produced two phenomena which jeopardize the lives of those exposed to their influence, viz , the great and rapid disengagement of carbonic acid, and notable diminution of oxygen in the air

The Spanish Cortes has passed a bill allowing cremation The dreadful scenes in Granada, where hundreds of bodies laid for days uncovered during the late cholera epidemic, no doubt influenced the the legislation Germany is also adopting cremation, and the Berlin *Verein fur Innere Medicin* has declared that the best authorities in the field of hygiene have clearly proved that cremation is the safest preventative against the spread of contagious diseases by corpses There were 186 cremations in Germany last year In Denmark the subject is exciting marked attention At the meeting of the Medical Sciences, held at Copenhagen, in 1884, Dr Lenson presented a report on the cemeteries of Denmark, and their influence on the public health After a most thorough and scientific investigation into the public health of Copenhagen he concludes that it has been repeatedly demonstrated that pestilential diseases have been traced to the use of water from streams or wells contaminated by the presence of cadaveric decomposition

Other schemes for the disposition of the dead have been urged Mr Pratt, of London, proposes to bury dead paupers in cheap coffins, to be cemented with concrete and used in building a breakwater at Heine Bay M Kergovtatz, of Brest, proposes rubbing a corpse with a chemical solution and plunging it into a metallic bath, investing it with an air-tight covering Gold, silver or copper could be employed, and the dead could thus be utilized as statuary

After reviewing in an exhaustive manner the testimony of medical experts, and setting forth the many and grave objections to the present mode of burial, Dr Morris said If incineration were accepted all these evils would be arrested It is generally admitted that this process should be adopted in all great epidemics and after battles, but it would be wise to extend it to cases of zymotic diseases, such as cholera, small pox, scarlet fever, and diphtheria These poisons are preserved for years, and at certain times under certain conditions vent their destructive force on the human race

FRIDAY, DECEMBER 11—FOURTH DAY

The Association was called to order at 9 55 A M , PRESIDENT REEVES in the Chair

The following were appointed the

COMMITTEE ON DISINFECTION OF RAGS

Drs G M Sternberg, J H Raymond, A R Smart, V S Vaughan, G H Rohe, Joseph Holt, and S H Durgin

The Committee on Disinfectants was continued for another year, and to it was referred Dr J H Raymond's resolution on *Disinfection of Sewers*

Drs Thos F Wood, of N Ca , S W Abbott, of Mass , and Smith Townshend, of Washington, were appointed a

COMMITTEE ON VACCINATION

The Executive Committee recommended that the

CONFERENCE OF STATE BOARDS OF HEALTH

be invited to become a section of the Association, privileged to elect its own Chairman and Secretary, and that the Executive Committee arrange for its meeting one day earlier than the regular session, and that one day, or a part of a day be set aside for the sole consideration of questions relating to State Boards of Health Adopted

ADDITIONAL LOMB PRIZES

It was then announced that Mr Lomb had decided to offer four additional prizes for the best plans for houses to cost $600, $1000, and $1500 These prizes are to be $100, $75, $50, and $25 each

A Committee of three, with Dr J S Billings as Chairman, was appointed to prepare a form for

YEARLY, MONTHLY AND WEEKLY MORTUARY REPORTS

The Advisory Council reported that it had considered the advisability of soliciting

GOVERNMENTAL AID IN PROSECUTING RESEARCHES INTO THE CAUSATION OF INFECTIOUS DISEASES,

and stated that the National Government had not made adequate provision for the study of such questions, either in the Army or Navy Departments, and it recommends that Congress be urged to appropriate necessary funds that these Departments may be properly equipped

The Advisory Council also endorsed Dr Joseph Holt's recommendation for a

A SCIENTIFIC COMMISSION TO INVESTIGATE YELLOW FEVER

The following were elected

OFFICERS FOR THE ENSUING YEAR

President—Henry P Walcott, of Massachusetts
First Vice-President—T S Covernton, of Toronto
Second Vice-President—G B Thornton, of Memphis
Treasurer—J Berrien Lindsley, of Nashville
Secretary—J Irving Watson, of Concord, N H

Toronto, Canada, was chosen as the place for the next annual meeting, on the first Tuesday in October, 1886 Memphis was strongly urged as the place of meeting, and the Association will probably go there in 1887

CHICAGO MEDICAL SOCIETY

Stated Meeting, January 4th, 1885

THE PRESIDENT, C T PARKES, M D , IN THE CHAIR

DR D R BROWER read a paper entitled

THE EFFECTS OF COCAINE ON THE CENTRAL NERVOUS SYSTEM

(See page 59)

DR E L HOLMES opened the discussion by saying that the South American Indians ate large quantities of the coca leaf, without injury

DR D R BROWER said that in the early history of Peru the Catholic Church authorities sought to stop the use of coca in that way because of its deleterious effects upon the people But it was impossible to do it, they used it clandestinely, and the prohibition was withdrawn Dr Brower said that used in that way the result was a similar condition of mental deterioration as that mentioned in the paper, while these people were capable, under its influence, of performing muscular efforts in climbing the hills and mountains of that country, they were a puny, sallow, emaciated people, with intellectual capacity very little above the brute creation

DR E L HOLMES said that his experience had been wholly in connection with local applications on the eye He had seen one case, in which he had placed cocaine in both eyes for an operation, in which it was followed by considerable depression and nausea through the night, but no alarming symptoms He had twice used it in his office for strabismus, placing a not unusual quantity in the eye, where the patient felt sick and almost slipped out of the chair, and the operation was performed with the patient lying on the floor, but he suspected it to be a fit of fainting at sight of the instruments He had found from experience that very minute doses will be absorbed, but had never seen the slightest influence from the amount which is usually given in the eye It is exceedingly satisfactory in performing operations, and in removing little motes and pieces of iron or steel lodged in the cornea

DR C W EARLE said it appeared to him that when Dr B was in the Washingtonian Home he got along with a very small amount of the drug, very much less than Dr Earle had anticipated it would be possible for him to get along with Dr B had informed him that he had been in the habit of taking from 15 to 18 grains a day After he went into the Home, the first three days he took less than grs iij, and after that time did not take any He regained his appetite very well, and appeared to improve in every respect up to the time that his wife and brother or brother in law came from Canada to visit him, then he was seized with an idea that he must go home, or at least to Canada, and from that time he was uneasy and did not do well Dr Earle said that it seemed to him that there had been more said in regard to the use of cocaine than there was any use in saying While Dr Bradley was at the Home he was not unlike an ordinary opium eater, they will all lie, and he would lie, and his friends would lie The depression which followed withdrawal was somewhat similar, although there were none of the symptoms of dizziness, or nausea and sneezing, which are usually present after the withdrawal of opium

DR SARAH HACKETT STEVENSON said that she was surprised at the deleterious effects found by Dr Brower from the use of cocaine in hay fever She had had a number of cases in which it was used, without any of the symptoms mentioned in the paper She used a 4 per cent solution, applying with a camel's-hair brush, or simply by snuffing Dr Stevenson said she had used cocaine a great deal hypodermically in surgical operations with good effect so far as anæsthesia was concerned

DR W F COLEMAN said there are two lines of practice in treating the narcotic habit, to cut a man off from his drug completely, at once, or to taper him off He believed in depriving him of the drug at once If he found a man being poisoned he would not add another dose, but stop it immediately He knew nothing practically of the internal use of cocaine, but was surprised at the grave effect mentioned by Dr Brower Cohn Mueller asserts that he kills a frog with four tenths of a grain, but to human patients he gave indiscriminately 5 grains and it produced no perceptible ill effect Locally Dr Coleman had had some experience with the drug, and there is this point about its immediate effect, it relieves pain in acute otitis but it is a grave question whether it does not prolong the case, and while it relieves pain it is doubtful if it is better than hot water or other remedies In its application to the eye there was not this objection, it produces anæsthesia and allows almost any operation to be performed without pain, it does not prolong congestion, and gives permanent relief

DR D W GRAHAM said that he noticed Dr Brower quoted a case reported by Dr Burchard in the *Medical Record*, in which a patient sustained loss of consciousness and stoppage of the pulse after an injection of four-fifths of a grain of cocaine Dr Graham doubted very much whether the bad effects were due to cocaine, we get the same effect in many patients by injecting water, or by showing them the hypodermic syringe, and he thought it probable that it was simply a fainting fit There was nothing in the report that would lead to any other conclusion except that Dr Burchard says it was the result of the injection of cocaine Dr Graham doubted the conclusion and thought it unreliable

Dr F M Weller said he had had some experience in the use both of cocaine and the fluid extract of coca He had never used such large doses as those mentioned, but had seen that very large doses of the drug would produce unpleasant symptoms about the head, dull heavy headache, something like doses of other narcotics Hypodermically he had used as much as five grains at one time without any unpleasant effects whatever He was inclined to think that the real difficulty in some of these cases was that some other circumstance was overlooked It seemed to him that some idiosyncrasy might exist that would make one peculiarly susceptible to this kind of narcotic, and it would hardly be reasonable to charge it all to cocaine His reading of the history of the use of the drug in South America, where it originated, led him to think that it could be used a long time without injury He thought one lesson is to be learned from the paper, viz, that no drug should be continued beyond the time of its necessity That principle laid down and strictly adhered to, the patient would never suffer from the deleterious use of any drug

Dr D R Brower in closing the discussion, said that Dr B bought cocaine wherever he could get it, and he did not know what preparation he used The other physician mentioned in the paper used Merck's cocaine altogether He used it for hay fever and took five grains by inhalation every day for ten days Dr Brower said that he did not suppose that such disastrous effects as occurred in these cases and others, would result unless there was some weakness of the nervous system, he thought possibly a person perfectly robust and with a well-governed nervous organization could take cocaine with impunity, but a person with a nervous temperament could not use this drug continuously without some such results following Dr Brower said his plan of treatment was that of gradual withdrawal, as well with opium and chloral as with cocaine This plan could be followed with less inconvenience to the patient Dr Brower said he was well aware that cocaine was one of the most valuable additions to the therapeutics of hay fever, it had been administered in perhaps thousands of cases in Chicago, and with few disastrous effects As to the case reported by Dr Burchard, the Dr reported it as a case resulting from hypodermic injection, and it struck Dr Brower as being a reasonable result in a very susceptible individual, but it might be that the man had a fainting fit The case was reported in the *Medical Record* of Dec 5, 1885, it impressed Dr Brower as being undoubtedly a case of cocaine poisoning

CHICAGO GYNECOLOGICAL SOCIETY

Stated Meeting, Friday Evening, Nov 27, 1885

THE PRESIDENT, DANIEL T NELSON, M D,
IN THE CHAIR

(*Continued from page 52*)

Dr Charles Warrington Earle presented for Dr Joseph Haven

A TERATOM, CORRESPONDING IN DEVELOPMENT TO THE THIRD MONTH, AND BEARING AN ASSERTED RESEMBLANCE TO A PUP

The following history was read Dr Haven had attended the family of Mrs H for the past four years During this time he had had occasion to notice that the younger daughter was a person unusually strong in her likes and dislikes, of a nervous temperament, slight build, yet a sensible, educated, and attractive girl On the eighth of September, 1885, this young lady in company with her sister, called at his office to consult him with reference to her condition He made the following entry in his case-book, as the result of her visit "Mrs D, 19 years old, married one and one half years, always regular as to her courses up to July 21, since then no show Physical signs point to pregnancy in the sixth week" A few days later he saw her again She was nervous and highly excited—almost hysterical She told him in an excited manner that a dog had jumped on her, and that she "hated dogs" She complained of pain in the abdomen, low down

From that day until the 1st of November, Dr Haven saw her several times Each time she was threatened with miscarriage, and each time she declared she was positive she could never carry that child Her husband and sister told him that, asleep or awake, her mind seemed to dwell continually upon that dog That she daily wondered if the child would be marked Mr D said that ever since he has known her she has been afraid of dogs, she would always cross the street rather than meet one, and he has often jokingly refused to take her out with him, telling her, as an excuse, that they might see a dog, and she would make a scene

On the night of November 1, the husband roused Dr Haven, desiring him to go over and see his wife, thinking it to be only a repetition of former attacks An examination proved that Mrs D was about to lose the contents of the uterus She was flowing constantly The os had dilated slightly and Dr Haven could just reach the presenting part The history of the miscarriage was the usual one, and the result is seen in the specimen presented She insisted on seeing the fœtus and declared it to be the image of the dog that had frightened her

Dr Charles Warrington Earle presented

SPECIMENS FROM A CASE OF ARTIFICIAL ABORTION

The fœtus corresponded in development to the fourth month of pregnancy, and was not decomposed It was closely enveloped in the membranes, and entire absence of the *liquor amnii* was noticed Hæmorrhage into the placenta and decidua was not observed

The following history of the case was read:

Mrs. F., American, has given birth to five children, the youngest 20 months old, labors always normal, has a history of anæmia for some months', if not years', standing, last menstruation ended May 20, 1885, in June had a very slight discharge of blood, during the weeks following she would occasionally lose a small amount of blood, at other times there would be profuse hæmorrhage lasting twenty-four hours. She had at one time a white, sticky discharge, something like the albumen of an egg. October 1, began to flow constantly with some pain in back and sides, particularly the left. Was seen by Dr. St. John October 12, at which time he administered the usual styptics with rest. She continued to flow, with pain, for another week, when hæmorrhage was so severe and prostration so pronounced, and with the suspicion of *placenta prævia* it was decided that temporizing means should cease. After consulting with Dr. Earle, it was decided to induce labor. A catheter was introduced and allowed to remain twenty-four hours, when pains came on and patient was delivered October 17, 1885. During the entire period of gestation the woman could not detect the usual signs of her former pregnancies. She made a good recovery and menstruated November 20. There had been no discharge of water perceptible to the lady during the entire period of pregnancy.

Dr. W. W. Jaggard thought Dr. Earle's case was a typical example of the condition, technically termed *mummification*. The fœtus dies, and the fluid constituents of its body and envelopes are generally resorbed. Mummification is usually observed in connection with twin pregnancies. One child is usually perfectly developed, while the other is converted into a mummy-like object.

Maceration and *mummification* of the fœtus are observed when the membranes are intact; *putrefaction*, after rupture and entrance of air into the uterine cavity. Dr. Earle's case was probably not an example of that rare condition, abnormally small amount of amniotic fluid. There were no abnormal amniotic foldings, nor the fœto-amniotic bands described by Simonart.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Insanity and Public Opinion—Double Popliteal Aneurism—Papilloma of the Bladder—A Large Calculus from a Boy's Bladder—The Mad-dog Scare—Typhoid Fever in Brooklyn.

At the last meeting of the New York County Medical Association Dr. J. R. MacGregor read a very elaborate paper on *Insanity and Public Opinion*, in which he referred to a number of ancient popular errors which still existed to a large extent, and pointed out the great need of a more enlightened sentiment in the community in regard to the matter.

This was followed by a paper on *Double Popliteal Aneurism*, by Dr. Ira B. Read. The case upon which it was based was one of great interest, as popliteal aneurism developed in the left lower extremity after a similar aneurism had been cured in the right, by ligation of the femoral artery. The second aneurism was treated in the same way, after an unsuccessful resort to pressure, which was also tried in the case of the first before operating. Having mentioned that both aneurismal tumors have now entirely disappeared, Dr. Read proceeded to discuss the etiology. In this instance, there was no history of a traumatic origin. The patient was a German about 30 years of age, of good habits, and with no suspicion of syphilis. The only external influence that he could fix upon as bearing at all on the case was the fact that the man, who was a grocer, was accustomed to go in his wagon to market every day or two and return with a load of groceries, and while thus engaged, the wagon would be so full that he was compelled to sit in a cramped position, with his legs flexed much beyond the point of comfort. "But," Dr. Read went on to say, "I cannot believe that this, without some internal predisposition, could have caused the trouble. If so, why are not the thousands of others who follow the same occupation similarly affected? Whether we look to age, sex, occupation, climate, or any external influence, I do not believe that we can assign any of them as primal causes in the production of aneurism. I believe we must look first to the condition of the artery itself. We will find degeneration, either atheromatous or calcareous, the cause of which we may or may not be able to discover. Having found this condition, I am willing to admit that age, occupation, or other conditions may act as exciting causes. From this, as a starting-point, I would say that those whose age or condition enfeebles them, those whose occupations most expose them, those who live in a climate which they do not well endure, would be most liable to suffer from aneurism." In the case in question, he found, as he had said, a possible exciting cause. There was also a possible predisposing cause. While there were no abnormal heart sounds, the action of the heart was at all times very violent, not in frequency, but in force, and all the medical men who saw the case recognized that it required a great weight to control the femoral artery. He would, therefore, say that in this case the excessive strain on the arteries, caused by an excessive action of the heart, was aided by the patient's occupation, as an exciting cause, in the production of these aneurisms.

In regard to the treatment of such aneurisms, he said that no method was devoid of great risk and responsibility. From his own experience he would lay down the rule that where compression can be made in the artery above the diseased portion, it should always be resorted to as a means of lessening the danger consequent upon ligation of the artery. In popliteal aneurism compression of the femoral below the profunda would cause the blood to knock more loudly at the door of the profunda, when it found that it could not gain admission to the femoral. "Thus," he said in conclusion, "it will gradually and surely distend the profunda and other smaller branches, and enable it more fully to carry on the work of the occluded femoral. If, in the meantime, you can succeed in filling the aneurismal sac with a clot, and thus effect a cure, so much the better, but if this result does not follow, and you must ligate the femoral, still, I say, so much the better. Thus may we carry to the limb below heat, nourishment, sensation, life, and thus give a wider berth to that dreaded sequel of ligation, death of the limb, and perhaps death of our patients.”

Dr. J. W. S. Gouley then presented several specimens of *papilloma of the bladder*, upon which he made some extended and instructive remarks, in the course of which he said that such tumors were not very common, but it was probable that they occurred more frequently than was generally supposed to be the case. As to their avulsion after opening the bladder through the perineum, probably the safest instrument for this procedure was that devised by Mr. Reginald Harrison, of Liverpool, in the use of which it was easy to avoid grasping other tissues beside the growth to be removed. In regard to the hypertrophy of the bladder not infrequently noticed in connection with such tumors, he said that whenever there was a foreign body or a growth of this kind in the bladder, concentric hypertrophy and contracture of the organ were apt to result, as time went on, from its continuous efforts to get rid of its contents by contraction. As to the cause of these papillomata, he believed that in each case there was some previous lesion which gave rise to the condition. This might be but a slight abrasion of the mucous membrane, caused, for instance, by a small calculus, which had afterwards passed away, but the granulations resulting from such an abrasion would be sufficient to afford a starting-point for the villous like growth. As to the intermittent character of the hæmorrhage in such cases, this was probably to be explained by the fact that the denudation of the membrane covering the growths which gave rise to the hæmorrhage was followed by an inflammatory process which blocked up the vessels, and thus prevented a further escape of blood. In reply to an inquiry whether he had in the diagnosis of these tumors made use of rectal examination, by introducing half the hand into the rectum, as recommended by some authorities, Dr. Gouley said that he had not, as he did not consider this procedure justifiable under ordinary circumstances, on account of the risk involved in it. Besides, it would be impossible to feel, through the thickened walls of the bladder, a soft growth of the character under consideration. A hard growth might be detected from the rectum, and in young subjects, where the prostate was so small, he was accustomed to practise digital exploration.

Dr. Joseph D. Bryant said that he had recently seen in consultation a case outside the State which he had every reason to believe was of the kind described by Dr. Gouley. At the time of his visit the patient was much prostrated, but he had advised perineal section as soon as his condition would warrant the operation. He said he would like to ask Dr. Gouley if there were not some definite symptoms which would enable us to make a diagnosis of papilloma of the bladder, as he thought it was now somewhat difficult to distinguish this from other vesical affections.

Dr. Gouley then expressed the opinion that a series of signs could undoubtedly be formulated which would be of sufficient diagnostic value to fulfil the requirements of the case. If there were a stone present, there might or might not be hæmorrhage. It was, however, very infrequent in young subjects, and, therefore, when hæmorrhage from the bladder occurred in an individual under 40, without any assignable cause, it was reasonable to suspect something of this sort. The peculiarity of hæmorrhage resulting from papilloma of the bladder was, that it came on at irregular intervals, and stopped spontaneously. Furthermore, the attacks increased in frequency and severity as time went on, and later there was cystitis, while the frequent contractions of the bladder in its efforts to expel this sponge like growth gave rise to concentric hypertrophy of its walls. But there was something better than symptoms, viz., a crucial test of the condition. In every suspected case it was the duty of the surgeon to pass an instrument through the urethra, and with it remove a small piece of the tumor, if any were present. By doing this and subjecting the portion of tissue thus removed to microscopic examination, he had now made the positive diagnosis of papilloma of the bladder in four cases. There was nothing new in this procedure, however, as Civiale had done the same thing fifty years ago. When there was any doubt about the diagnosis, an exploratory incision through the perineum he believed to be perfectly justifiable.

One of the cases described by Dr. Gouley was that of a young physician whom he first saw about six months ago. In this instance the diagnosis was made by removing a portion of the growth with a pair of small forceps, but the doctor had as yet declined to have the operation of cystotomy performed. There had now been no hæmorrhage for a considerable time in this case, but he felt confident that it would inevitably recur in time.

At the conclusion of the discussion of Dr. Gouley's remarks Dr. T. R. Varick, of Jersey City, presented a very large stone which he had recently removed from the bladder of a boy 14 years of age. It weighed seven ounces and four scruples, Troy weight, measuring six and three-fourths inches in one circumference and five and one half inches in another. The patient had borne the operation well, and was now in a fair way to recovery.

One of the morning papers has taken a very sensible stand in protesting against the mischievous and demoralizing “mad dog scare” which has been wrought up as the consequence of the biting of the children in Newark by a stray dog. Pasteur's experiments with inoculation and the determination to send the children to Paris gave the cases an unusual interest, but there was no ground for the senseless excitement that has been aroused. It is possible that this dog was mad, and it was perfectly right that every precaution should be taken against the possible results of the bites inflicted by him, but there is not the least evidence of an epidemic of rabies among dogs, or any greater liability to the malady now than at any other time. It is by no means certain, however, that even this one dog really had the disease, and not a single other case has been substantiated Yet, "if a dog has a fit now, all the people of the vicinage are scared, and he is killed and reported rabid Throughout New Jersey every stray cur is stoned into desperation, and shot down and added to the list If a person happens to be bitten by any ill natured or irritated creature of the canine species, he at once imagines himself in danger of hydrophobia, and is in a fair way to work himself into convulsions from sheer fright The result of all this folly is an infinite deal of discomfort to people whose apprehensions are excited, and no end of thoughtless cruelty to innocent and harmless dogs" The craze has extended in a somewhat mitigated form to this city, and the Board of Aldermen, responding to senseless and frantic appeals from irresponsible sources, has furbished up its neglected dog ordinance, and the pound is to be reopened for the encouragement of dog stealing

Charles Kaufmann, of Franklin, N J, who was bitten by a dog on November 21, and Ludwig R Sattler, a veterinary of Orange, N J, who was bitten December 13, have both arrived in Paris, and been inoculated by Pasteur, but there is no sufficient evidence to show that the dog actually had rabies in either instance

There were reported between November 1 and December 15 at the Health Office in Brooklyn 165 cases of typhoid fever, with a mortality of about 50 cases, while the average annual number of deaths from typhoid in that city for the last ten years has been eighty-five A partial house-to house inspection has already shown the existence of defective and dangerous plumbing in no less than 609 houses in the affected districts, but it is said that this inspection must now be discontinued for lack of funds The health authorities ought certainly to be upheld in their efforts to seek out and remedy the causes of such filth diseases, and if the facts of the case are plainly presented to the public, it would seem that ample means ought to be promptly furnished for carrying on the good work P B P

LETTER FROM PHILADELPHIA

(FROM AN OCCASIONAL CORRESPONDENT)

The Annual Meeting of the Societies—Election of Officers by the County Medical Society—Election of Delegates to the Association Meeting—The Appointment of Dr Flint to deliver the Address in Medicine before the British Medical Association—Dr Philip Leidy

As usual, this the first of the new year finds our medical societies engaged in the annual selection of their officers The daily papers are also filled with the names of medical men selected as attendants for the various hospitals and other charities for which our city is justly celebrated Perhaps the most interesting and most truly exciting meeting thus far held, was that of the County Medical Society This is the only organization in our city which is entitled to send delegates to the State and National Associations At the annual election on Wednesday afternoon last, there was an unusual display of feeling in reference to the action of the American Medical Asssociation in New Orleans last May It was whispered about for a few days prior to the meeting, that some effort would be made to commit the County Society to the side of the malcontents, and thus enable them to succeed in their efforts at obstructing the meeting of the International Congress of 1887

Last October, in accordance with a special law of the County Society, which says "Nominations for delegates shall be made at the stated meeting in October by a nominating committee named at the stated meeting in June, which committee shall present a ticket of candidates for election to the different delegations of the Society," this nominating committee presented a ticket of nominations of delegates to the American Medical, and the State Medical Societies This report was received without a dissenting voice, and, as usual, a copy was sent by the Assistant Secretary to each member of the Society, with the notice for the January meeting A day or two prior to this meeting, some of the members received a circular asking them to support a different ticket, to quote their words, "Nominated in the interests of general professional harmony" It does not appear as though any effort was made either by the members of the nominating committee or by their nominees When the Society was assembled, the first move was to suspend the order of business in order to introduce, in violation of the by laws, a ticket not named by the nominating committee, this was on the motion of Dr Agnew, who, seemed to be the leader of the opposition to the regularly named ticket This proposition was opposed by some of the oldest members, and especially by several of the ex-Presidents, as not in order Now commenced a most remarkable scene Hisses, jeers, cries of "order" were hurled full in the faces of the little party thus standing up for the rules and asking that they be obeyed The President seemed utterly powerless, or disinclined to stem the flood that carried all before it The "Ayes" and "Nays" were demanded and yielded to with great reluctance The call showed that out of a membership of over four hundred, about one hundred and fifty were in favor, to fifty against the substitution of the new ticket Of course, after this vote, the ballot was a mere form, and resulted in about the same figures, or even with less opposition, owing to the fact that many now left the room disgusted

During the balloting Dr Agnew offered a series of resolutions condemning the action of the American Medical Association, and requiring the Philadelphia delegates to vote for a reversal of its action These resolutions will no doubt be shortly sent you by the Secretary of the Society It was fully and even boastfully acknowledged by several that they had come to carry their point, even if it required the setting aside of all the laws of the Society While some of these gentlemen publicly announce their adherence to and regard for the Code of Ethics, yet more than one expressed a belief that this was the entering wedge toward the adoption of the New Code, or the destruction of the Medical Society, and one even hoped for these results, as he desired to be free It was suggested in the conversation which followed in the little group around him, that his proper plan was to resign, but he seemed to prefer to wait within the lines while constantly chafing at the restriction imposed upon him

The leaders, and those who spoke in behalf of the opposition, announced themselves as "pacificators," endeavoring to promote the harmony of the profession, but the remarkable method which they have adopted has thus far been productive of a decidedly different effect It is the cause of most bitter talk in every accidental meeting of medical men, and the daily papers are jocosely predicting in this disagreement of the doctors, a great increase in the sales of patent medicines

It is a well known fact, announced at the meeting, that at least one gentleman on the ticket thus elected is not a member of the County Society, and it is a question whether several were elegible by reason of non payment of dues The question of the legality of this election may yet be brought before the Censors, or even require a decision of the Judicial Council

A dinner was given to Dr Samuel R Knight, the efficient superintendent of the Episcopal Hospital, on Thursday evening, at Warmley's, No 931 Girard avenue More than forty physicians sat down, and the occasion was a very pleasant one

The appointment of Dr Austin Flint to deliver the Address in Medicine before the British Medical Association at its session next August, has been a source of much gratification to his numerous friends in this city

Our Board of Guardians have just deposed Dr Richardson as Resident Physician of the Insane Department of our Almshouse, and elected Dr Philip Leidy, a brother of the well known anatomist, Prof Joseph Leidy Dr Leidy seemes to be entering upon his new duties with an earnest determination to prove of service to his unfortunate wards It must be remembered that this department has more than one hundred patients beyond its fullest capacity for the proper care of the insane More than half of the patients are necessarily compelled to sleep upon the floor Dr Leidy believes that many can be better accommodated at their homes or in the Almshouse proper "Some have been in this department for years without having manifested any marked evidence of insanity " Dr Leidy found that many had been unnecessarily deprived of out door exercise Let us hope for him the fullest success in his benevolent work

January 9, 1886

INOCULATION FROM THE PUSTULE OF TARTAR EMETIC TO PREVENT SMALL-POX

To the Editor of the Journal

Dear Sir —With similar facts that might be cited, the interesting observations of Dr de Mello, of Rio de Janeiro, and Dr B S Woodworth, of Ft Wayne, Ind , in recent numbers of The Journal, upon the spontaneous origin and identity of yellow fever with malarial disease, support the views presented in my paper on the "Unity and Nature of Morbific Poison," in the first volume of The Journal for 1885, p 174, and in my work on the "Basic Pathology and Specific Treatment of Zymotic, Septic, and Allied Diseases," in which evidence is adduced of the general unity of cause and nature, with *de novo* origin, of all such maladies, and the proper means for their prevention and treatment

But what I desire to invite special attention to at present, is with regard to the apparent identity of the tartar emetic with the vaccine and small pox pustule, both in appearance and prophylactive power against that destructive malady, which Dr Woodworth so specifically refers to in his incidental statement of the close resemblance or mimicry of the first and last, and the probable protective value of the former with vaccination Now, many years ago it was stated in some of the journals, that a German investigator, whose name (and the publication) I do not clearly recall, had experimentally shown that inoculated pus from the tartar emetic pustule produced a pustule so much like that from the vaccine virus that they could not be distinguished from each other, and, what is more remarkable, afforded the same protection against variola as vaccination itself If my memory serves me aright, he thus inoculated and protected quite a number of men, women and children successfully, as demonstrated by their subsequent exposure to and preservation from the contagion of small pox

These facts or observations and speculations open up a new and wonderful field of investigation, with promising usefulness of the highest value in practical medicine—both preventive and curative—that should be taken advantage of by every physician having an opportunity, which is often presented in the casual outbreak of isolated cases or epidemics of this dreadful variolous malady, in the absence of any vaccine virus, and the adequate means it affords of protecting by vaccination the unfortunate people exposed thereto Now, as it is the bounden duty of every practitioner to resort to all possible means of protection in such an emergency, it would be obligatory thereupon to utilize this promising safeguard, and further test the matter by inoculating with the pus from the tartar emetic pustule, as well as by the production of the latter alone, as suggested by Dr Woodworth, it being apparently identical with that of variola, "that pustules produced by tartar emetic *may* be as good a preventive of small pox as the vaccine virus " If, however, this be true, it would necessarily follow that those who were pustulated with tartar emetic for other purposes would thus be protected against variola, which is, hence, an important subject of inquiry Therefore, as this prophylactive method has been experimentally tested with asserted success to a certain extent, it is not only a right thing to do, but even imperative upon every member of the profession, in all cases of necessity to thus act on the probabilities and give exposed persons the benefit of the doubt for their protection from variola by this form of tartar emetic pustule inoculation, until the more certain mode of prophylaxis could be secured by vaccination, especially as the means therefor are always at hand, and it is a simple, safe, inexpensive, and convenient plan of probable protection against one of the direst maladies

But, independent of such contingencies, this question could largely, if not positively, be determined by comparative experimentation on the lower animals. Thus, for instance, tartar emetic pustules could be developed on, as well as the pus therefrom inoculated into the udder of a heifer, followed, after the healing and subsidence of the consequent local and constitutional effects, by the insertion of variolous or vaccine matter to ascertain whether either or both would "take." Or either of the two, variolous or vaccine virus, with the pus or pustule of the tartar emetic, might be introduced simultaneously in different parts of the same udder or animal to determine whether there was any relative controlling influence exercised upon each other. The same plan might be adopted in human beings, as in double or multiple vaccination, with the latter first and then tartar emetic pus or pustule, and conversely, or both at the same time in different parts of the body.

Thus, by these and other safe experiments, this important question of the protective efficiency of tartar emetic pustule or pus against variola might be settled, and if true might be an invaluable discovery, besides would doubtless develop collateral knowledge of the greatest practical value to both mankind and the inferior creatures. At all events, it opens up a new field for investigation, which those who have the the opportunity could cultivate with advantage to themselves, science, humanity, and the lower forms of life.

GEO. J. ZIEGLER, M.D.

Philadelphia, January 9th, 1885.

BOOK REVIEWS.

A MANUAL OF OPERATIVE SURGERY. By LEWIS A. STIMSON, B.A., M.D., Surgeon to the Presbyterian and Bellevue Hospitals, New York, etc. Second Edition. 8vo, pp. xxiv, 506, 342 illustrations. Philadelphia: Lea Brothers & Co., 1885. Chicago: Jansen, McClurg & Co.

Dr. Stimson tells us in his preface that in preparing the second edition of this work he has sought to indicate the changes that have been effected in operative methods and procedures by the adoption of antiseptic methods, and to describe such additions and substitutions as have been favorably received, the chief alterations and additions being found in the passages treating of excision of bones and joints, and of operations on the peritoneal cavity. The reputation of the author is quite sufficient guarantee that the work has been well done, but to see how well it has been done we must read the book. In the way of a manual of operative surgery it is all that can be desired.

A TEXT-BOOK OF PHARMACOLOGY, THERAPEUTICS AND MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., F.R.C.S., etc. Adapted to United States Pharmacopœia by FRANCIS H. WILLIAMS, M.D. 8vo, pp. 1035. Philadelphia: Lea Brothers & Co. 1885. Chicago: Janseh, McClurg & Co.

This work merits praise. Its arrangement is somewhat novel, and adapts it especially for use by students of medicine who are not only trained by didactic lectures but also by laboratory exercises on the physiological action of drugs.

In order to save repetition the author devotes the first part of the book to a description of the methods employed for discovering the physiological action of drugs upon the various organs of the body. Not only does this enable him to avoid repetition, but also to contrast clearly the action of various drugs on the same tissue or organ. The first chapters of this section are devoted to a consideration of "Circumstances which Affect the Action of Drugs," such as fasting, habit, climate, etc., and the action of drugs on blood and the lower organisms. In the remaining chapters the action of medicines upon individual tissues and organs is considered. Chapters are devoted to the action of drugs on muscles, nerves, spinal cords, brain, special senses, respiration, circulation, digestion, tissue change, excretions and generative system.

This portion of the work is excellent. Much information is given of a purely physiological character. This, however, is quite necessary in order to understand readily the changes produced by drugs.

The last half of the work is devoted to a concise consideration of the subjects of Materia Medica. The preparations, properties, tests, doses, actions and uses of each drug are given. Drugs belonging to Inorganic Materia Medica are first described, then those of Organic, Vegetable, and lastly Animal Materia Medica. The two last groups are taken up in the order of their natural classification.

The author is so well known for careful and faithful work that further comment is scarcely necessary. The book can be used advantageously as a text-book in any college, but to the best advantage in those in which instruction is given in the physiological laboratory as well as in the lecture room.

THE PRINCIPLES AND PRACTICE OF MEDICINE. By CHARLES HILTON FAGGE, M.D., F.R.C.P., Physician to, and Lecturer on Pathology at, Guy's Hospital, etc. Vol. I. 8vo, pp. xv, 1040. Philadelphia: P. Blakiston, Son & Co., 1886. Chicago: W. T. Keener.

Since all who know anything of Dr. Fagge know that he was a very learned man, and a hard and most methodical worker, we must regret that this work was not published under his immediate supervision. The book is a strange mixture of satisfactory information and unsatisfactory generality. It is painful to be obliged to say this of the work on which the lamented Fagge spent the last twelve years of his life. It is in the matter of treatment that the work is most unsatisfactory, in dealing with other things the book is almost cyclopædic in the information contained in it. The first volume treats of "General Morbid Processes," "Specific Diseases," "Diseases of the Nervous System," and of the "Respiratory Organs." The arrangement of the chapters, sections and subsections is deplorably bad, reflecting alike on the editor and the publisher, and the first volume of 1040 pages appears without an idea. No definite order seems to have been followed out in treating of diseases or any one disease

In spite of these defects we must feel that there is an immense amount of valuable material in the work, and that it would contain very much more could the distinguished author have lived to see it through the press The chapter on "Fever," the third in the book, is very interesting and instructive, as are, more particularly, the Sections on "Diseases of the Nervous System" and on the "Neuroses" To few books would we more willingly have given unrestricted praise than to this We can but hope that, for the good of the second volume, the editor and, especially, the English publisher have had their attention called to the more prominent faults in the first

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the JOURNAL for one year from the following July Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

RICHARD J DUNGLISON, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

MEDICAL SOCIETY OF THE STATE OF NEW YORK —The eightieth annual meeting of this Society will be held in the Common Council chamber, City Hall, Albany, on the 2d, 3d and 4th days of February, 1886

SECRETARY OF THE SECTION OF OBSTETRICS AND GYNECOLOGY OF THE AMERICAN MEDICAL ASSOCIATION —In a recent issue of THE JOURNAL we gave the addresses of the officers of the several Sections of the Association In doing so, Charles T Paine, M D , of Comanche, Texas, was given as Secretary of the Section of Obstetrics and Gynecology We are informed from a reliable source that we should have given the name of J F Y Paine M D , of Galveston, Texas, as the Secretary of that Section The official minutes of the Secretary of the Association do not give the initials of Dr Paine, which gave rise to the error mentioned

BEQUEST FOR THE ADVANCEMENT OF SCIENCE —It is stated that about $25,000 has accumulated under a bequest of Mrs Elizabeth Thompson, who desires the sum to be appropriated "for the advancement and prosecution of scientific research in its broadest sense" Applications for grants out of this sum should be made to Dr S C Minot, 25 Mt Vernon St , Boston, Mass The first appropriations will be made early in the present year

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JANUARY 2 1886 TO JANUARY 8 1886

Major Chas E Goddard, Surgeon, died at Ft Yates, D T , Jan 4, 1886

Capt Curtis E Munn, Asst Surgeon, ordered from Dept East to Dept Columbia

Capt Wm C Shannon, Asst Surgeon, ordered from Dept Platte to Dept East (S O 4, A G O , Jan 6, 1886)

First Lieut W D McCaw, Asst Surgeon, relieved from duty at Ft Lyon, Col , and ordered for duty at Ft Leavenworth, Kan (S O 1, Dept Mo , Jan 4, 1886)

ORIGINAL LECTURES

CARCINOMA OF THE CERVIX UTERI—TALIPES EQUINUS—FISTULA IN ANO

A Clinical Lecture Delivered at the Mercy Hospital, Chicago, December 5, 1885

BY EDMUND ANDREWS, M D, LL D,
SURGEON TO THE HOSPITAL
(REPORTED BY W G BAILEY)

This case appears to be cancer of the uterus. It is at least a fungous tumor, two and a half inches in diameter, filling the upper part of the vagina. It does not seem to have any adhesions to the walls of the vagina, but only to the cervix uteri. I will remove it cautiously, as the operation may be attended with some hæmorrhage, which we will check if necessary. I will first use the *ecraseur* to remove the great body of the tumor, then I can use the curette. This growth covers nearly the entire cervix, so that I shall be obliged to remove its base by scraping. The body of the mass is now removed. The base of the growth is tough and does not yield to scraping very readily. We cannot, you know, cut very freely in this vicinity for fear of wounding the peritoneum. There is not so much hæmorrhage as I had expected, though a small artery is to be seen pumping out its contents. I have trimmed away everything that can, with safety, be removed by the scoop, and will now make use of a little chromic acid to cauterize what remnants there may be left of the malignant tissue, and wipe out the parts so that the surrounding tissues may not be irritated by the caustic. We will then treat the wound antiseptically. The hæmorrhage has nearly ceased, only a faint oozing can be detected. The extent of this cancerous growth over the cervix was so great that I am not as cheerful about a cure being effected as I otherwise should be.

In a day or two I will make a specular examination and, if I find the wound in good condition, will cauterize the parts again. Using the scoop in this instance, was very good practice, but was not of sufficient utility, so the cautery was used. An ordinary bone scoop is about as good as any you can use for most purposes, and when the tissues are tough, as in this instance, it takes hold better than the curette.

Double Hare lip—Re operation.—The former operation has given us a good union of the lip part, but the columella that I made for the nose did not unite with the top of the lip. I must make a perfect union. Adhesive plasters will not be of much service in this case. I will pass silver sutures through the lip and septum of the nose and draw the parts together. Having now firmly restitched the parts, I will send the child to the nurse.

Tenotomy of Tendo Achillis.—This patient has at some former time had hip joint disease, the head of the femur has been destroyed. If it had been a dislocation with shortening to this extent we should have had a rotating inwards of the head of the femur, as the inward rotation is absent, it proves that the head of the femur was destroyed by the former disease. The tendo Achillis is so short that it draws the young lady's heel upward, thus producing the deformity talipes equinus. The patient as already stated, has one limb much shortened from former hip disease, and must wear an elevated shoe. If she does not have the talipes cured, the down sloping foot will always slide down the inclined plane of the sole, crowding the toes together into the tip of the shoe, and producing both corns and painful deformities, hence the sole of the foot must be brought to the horizontal position. We will perform tenotomy upon the tendo Achillis. I take the tenotome in my fingers, and insert it between the skin and the tendon, and then, turning the edge towards the tendon, sever the latter by a cautious stroke, now place a piece of adhesive plaster over the wound, and over the plaster a piece of Lister's antiseptic gauze, and cover all with a dressing of oiled silk, or oiled or waxed paper, any one of which makes an antiseptic covering. The whole will be retained in place by a bandage. In a day or two, tension will be applied to bring the foot to position.

Fistula in Ano, with Sphacelus of the Scrotum.—This man is a coachman and a favorite of the family with whom he lived, presumably, therefore, his habits are good, and his present condition not due either to intemperate habits or bad hygiene. He has had dysentery for some weeks at his home, and was attended by a physician of superior skill. The inflammation was first simply in the mucous membrane of the rectum and colon, it grew more intense, and penetrated all of the coats of the intestine, until, finally the connective tissue surrounding the rectum mortified, the walls of the rectum partially sloughed away, and a large fistula was formed. His softened fæces readily passed through the fistula into the ischio rectal fossa, thus inflaming that part, and poisoning, more or less, his whole system, the inflammatory process has extended along the perineal subcutaneous tissue to the dartoid tissue of the scrotum, and in this region produced a redness that pitted on pressure, like erysipelas Then the skin of the scrotum mortified I fear for his life because of his condition, though the disease has not been of long duration and his system does not seem to be hopelessly poisoned as yet I opened the scrotum yesterday to let out a quantity of serum that had collected there It does not follow that a man must die because of a local spontaneous gangrene I have seen cases in which almost the entire skin of the scrotum sloughed off, and the patients have made good recoveries His temperature has never risen very high, he has been taking the tincture of the chloride of iron and quinine, and in view of these facts, perhaps he is in better condition than one would suppose Where the abscess broke externally, a black gangrenous orifice is plainly visible Inserting my finger in the fistula, I can, without any difficulty, push it along the perineum to the scrotum Introducing my finger in the rectum, I find a large fistula connecting that viscus with the ischio rectal fossa With a probe-pointed bistoury, I will sever the tissues between the rectum and the external opening of the abscess, and also make another incision along the undermined perineum towards the scrotum Having freely opened the parts, I find a great mass of mortified connective tissue alongside the rectum, and a smaller one extending forward beneath the skin of the perineum as far as to the mortified patch on the scrotum This dead connective tissue is already loose, and we draw it out, as you see, without difficulty It is very putrid and horribly offensive I will now take my scissors and clip off the loose dead skin and dartoid tissue from the scrotum I hope the removal of this terrible mass of decomposing tissue may prevent the blood-poisoning from being fatal The parts will now be thoroughly sponged and syringed out with corrosive sublimate water, and the patient be taken to his room (In this case the dysentery recurred again, followed by gastritis and death)

THE PULMONARY COMPLICATIONS OF TYPHOID FEVER[1]

BY F B HARRINGTON, M D,

OF BOSTON MASS

TYPHOID FEVER COMPLICATED BY CIRCUMSCRIBED PNEUMONIA

Case 1 Miss G, 25 years old, was seen November 10, 1884 The temperature was 104 5°, the pulse 108, and the respiration 32 For five days she had been feeling poorly, and had suffered with headache and nausea She had a chill and there had been some cough The tongue was heavily coated The bowels were regular On examining the chest a region of dulness was found at the base of the right lung in front The dulness did not extend above the nipple, and was not marked In the back it was wanting Over this area moist râles with slightly prolonged expiratory sounds could be heard Before the present illness there had been no cough

The abdomen was slightly tympanitic, and there was slight tenderness in the left iliac region

November 11 On the following day the temperature rose to 105 2° Diarrhœa and some cough

November 12 Temperature 104 9° Diarrhœa and cough

November 13 The temperature 104 7° The cough was slightly increased and the expectoration, previously viscid mucus, became rusty in color The dulness had increased slightly in intensity though not in area Fine and course râles were abundant and respiration was somewhat bronchial There was some deafness For several days the patient seemed to improve and the temperature fell to 99 2° on the 16th The rusty expectoration disappeared and the cough became less The diarrhœa continued On the 19th she complained of pain in the region of the rectum, and a poultice was applied to a spot of tenderness

November 22 A large ischio rectal abscess was opened by incision, and the rush of pus and gas showed that it had perforated the rectum

From this time on the patient gradually grew worse

November 25 There was mild delirium, which changed two days later to active delirium The pulse was gradually becoming weaker There were abundant râles in both bases behind

The abscess continued to discharge

December 2 The patient died For two or three days before death there had been an increasing dulness at the bases of both lungs, due to the constantly increasing weakness of the heart

TYPHOID FEVER WITH HÆMOPTYSIS DURING CONVALESCENCE

Case 2 Mr C, of phthisical family, 28 years of age, after the usual preliminary symptoms of typhoid fever, went to bed January 22, with headache, coated tongue and pain in the right iliac fossa Diarrhœa began three days later The patient went through a mild attack of typhoid, and a little over three weeks after the attack the pulse became normal with a slight evening rise The pulse was now 96 and weak The temperature never rose above 103° Considering the moderate temperature and the lack of exhausting symptoms there was very decided prostration About this time a slight cough developed, but gave little trouble, and the chest was not examined The improvement in the patient was very slow At the end of a month the patient sat up for a short time, but was very weak Two months after he was attacked he was still unable to be about His cough had become more troublesome On examining the chest nothing abnormal was found The pulse was rapid and weak, this was March 17 Nine days later I was called and found the patient suffering from a profuse hæmorrhage following a fit of coughing At the left apex I found fine and coarse râles with dulness and slightly prolonged expiratory murmur Two weeks later there was a second though less copious hæmorrhage A month later the patient had so improved that he was able to walk out The cough continued and still exists, though the man is now about his business

---

[1] Read before the Section for Clinical Medicine Pathology and Hygiene of the Suffolk District Medical Society, December 9 1885

No disease is so prolific of complication as typhoid fever No structure of the body escapes entirely No function is safe Rupture of muscles, necrosis of bones, abscess of the liver, gangrene of the lungs, loss of sight, aphasia and insanity are but a few of the rarer complications There are two important causes for this multiplicity of lesions The first and most important cause is the duration and severity of the pyrexia The second cause, less demonstrable, is the specific poison of the disease The continued high fever causes parenchymatous changes in all the organs Hoffmann[1] found only 56 cases out of 161 autopsies in which the heart muscle was normal or nearly so The power of the heart is greatly lessened The circulation is impaired and the nutrition of the parts suffers The respiratory complications in typhoid fever are numerous Out of 111 autopsies, from Biermer's clinic, the respiratory apparatus was perfectly healthy in only two instances, according to de Cèrenville Bertz[3] makes a report of 899 cases of typhoid fever from Ziemssen's clinic from 1878 to 1883 Among a large number of complications were the following pulmonary, or intimately associated with pulmonary lesions —

Typhoid fever in Ziemssen's clinic from 1878 to 1883 Beetz [4]—

Bronchitis	59
Croupous Pneumonia	41
Catarrhal Pneumonia	14
Hypostatic Pneumonia	10
Hæmorrhagic Infarction	2
Pleurisy with Effusion	22
Old Pleuritic Adhesions	2
Pulmonary Phthisis	19
Miliary Tuberculosis	2
Pleuropneumonia	4
Pulmonary Emphysema	4
Gangrene of the lungs	1
Apex Induration	6
Abscess of Lung	2

Making a total of 188 out of 899 cases

A *report of* 250 *autopsies* after typhoid fever at Basle Hoffmann [5]—

Splenization	35
Lobular Pneumonia	38
Lobar Pneumonia	18
Pleurisy	20
Pneumothorax	1
Hæmorrhagic Infarction	15
Miliary Tuberculosis	4

Goeltdammer, in a report of 783 cases occurring at Berlin in 1874, 1875 and 1876,[6] says bronchitis was wanting in only the lightest cases Hypostatic congestion was found in 40 of those who recovered, and in about one-half of those who died (There were 130 deaths)

Lobar pneumonia existed in 11 cases, only one of which recovered Embolic pneumonia was the cause of death in five cases There were 13 cases of pleurisy, eight of which died There was one case of phthisis

Hoffmann, in a report of 250 autopsies at Basle, says[1] that bronchial catarrh extending to the finer bronchi almost always accompanied the early intestinal changes He found —

Splenization	35
Lobular Pneumonia	38
Lobar Pneumonia	18
Pleurisy	20
Pneumothorax	1
Hæmorrhagic Infarction	15
Miliary Tuberculosis	4

Two of the eighteen cases of lobar pneumonia occurred at the outset of the disease, and will be referred to again

I have included under the heading "Pulmonary Complication," not only true pulmonary lesion, but also lesion of parts intimately associated, as the bronchi and pleura

The signs of pulmonary lesion occurring with typhoid fever are usually marked to a greater or less extent Characteristic expectoration in pneumonia is often wanting Cough in bronchitis is frequently absent When respiratory lesions are epidemic, as might be expected, there is an increased amount of complication with typhoid fever Children are found to be more subject to these complications than adults

As has been already said, bronchitis is rarely wanting in typhoid fever Lichermeister says [2] "Catarrh of the smaller bronchi is so frequent in typhoid fever, that a certain diagnostic significance may be attached to its occurrence" It may be so slight as to cause little or no trouble, or may be, and especially in children, a very serious complication One of the chief dangers of this bronchitis is that owing to the great general weakness, the secretion may not be thrown off, and atelectasis and broncho pneumonia may result Lobular pneumonia is a common occurrence in typhoid fever A Weil,[3] owing to the lack of signs, considers it very difficult to differentiate the various forms of consolidation occurring in typhoid fever He is often unable to determine clinically, whether the consolidation be due to atelectasis, to hypostasis, to lobar or lobular inflammation, or, as often happens, to a combination of these conditions *Lobular pneumonia* is the most common form of pneumonia occurring in typhoid fever It rarely begins with a chill, but there is almost always an increase in the temperature

Lobar (*croupous*) *pneumonia* sometimes occurs during convalescence At this period it does not differ in any way from an ordinary attack of that disease There is usually the sharp attack with chill and sudden rise of temperature, dyspnœa, characteristic expectoration and râles When croupous pneumonia complicates typhoid fever of the second and third weeks, during the height of the disease, many of the ordinary characteristics are wanting According to

Homalle,[1] the chill is often wanting, there may be no rise in temperature, pain is absent or of short duration, characteristic expectoration and râles are seldom present and the cough is infrequent

Lobar pneumonia, occurring during the first two weeks of typhoid fever, is the subject of much discussion It sometimes occurs as a simple complication, and at other times there seems to exist a kind of transition form between the two diseases

Lepine[2] in his article on "pneumonia," expresses his belief in a form of pneumonia due to the local infection of typhoid fever, in which the pulmonary symptoms are the noticeable ones, and the abdominal symptoms are slight This he calls pneumo typhoid Hoffmann[3] classes two of the 18 cases of lobar pneumonia which he found as pneumo typhoid A short history of one of these cases will illustrate the disease

Mr E, 21 years of age, began to suffer with headache, September 4, and had nosebleed September 13 went to the hospital The breathing was labored, there were râles in both lungs and dulness and bronchial breathing in the lower right lung On the 18th the patient died On autopsy, croupous pneumonia of the right side and infiltration of Peyer's patches and ulceration of the ilium were found Had the latter lesions been absent, Hoffmann would have considered the case one of pneumonia with typhoid symptoms [Typhoid pneumonia Flint]

Longet[4] thinks that there are cases of pneumo-typhoid in which there are no intestinal symptoms, and in which on autopsy no intestinal lesion can be found He believes that typhoid poison in severe cases makes its entrance through the lungs or has its seat there E Wagner,[5] in concluding an article on the subject of pneumo typhoid, says that, with our present knowledge, it is impossible for us to decide the exact neurological position of the disease Exact knowledge of the specific germ of the disease will clear this doubt

Cardiac weakness, so common in typhoid fever, is a direct cause of several of the pulmonary complications These complications are in no way peculiar to typhoid fever, but may occur in any asthenic fever They are more common in typhoid fever on account of the duration and intensity of the fever Passive congestion of the lungs often occurs as the result of cardiac weakness This passive congestion may lead to œdema The passive congestion is most likely to occur in dependent portions of the lungs It may be unilateral if the patient for any cause has assumed a position upon one side, but when it occurs it is usually bilateral This form of congestion has been called hypostatic When the parts, through œdema, become devoid of air, an appearance resembling the spleen may be seen This is splenization Another result of feeble action of the heart is the formation of thrombi These becoming detached, may cause embolic infarction of the lungs Emboli may arise from some septic source Goldtdammer[6] reports five deaths from embolic pneumonia among 783 cases of typhoid fever The origin of the emboli was in one case the right side of the heart, in another an old perityphlitic abscess, in a third case an abscess of the thigh The origin in the other cases was not discovered These emboli may cause gangrene of the lungs, and the pulmonary tissues breaking down, pneumothorax may result Embolism of the pulmonary artery and instant death is not a rare occurrence

Like pneumonia, pleurisy in typhoid fever may give little indication of its presence It occurs frequently, but unless extensive, it is very apt to escape notice Empyema also occurs, and sometimes independently of pneumothorax Acute miliary tuberculosis sometimes occurs as a sequel to typhoid fever, but probably not from any direct cause Phthisis also develops sometimes as a result of the non-absorption of secretions which have not been thrown off during the period of great prostration

Hæmoptysis, according to Homalle,[1] occurs during typhoid as the result of a hæmorrhagic infarction It may also occur as a symptom of concurrent phthisis

The extreme exhaustion of many typhoid cases makes the frequent examination of the patient more difficult For this reason and from the lack of symptoms many of the above complications undoubtedly exist at times and escape unnoticed Given a severe case of fever with high temperature and marked abdominal symptoms, diarrhœa, abdominal distension and tenderness with more or less stupor, is the frequent examination of the patient's chest, requiring moving of the patient, necessary or desirable? Flint advises the frequent change of the position of the patient with a view to prevent hypostasis This certainly is desirable Patients who have kept a fixed position for a long time will often give signs of hypostasis, which will disappear on assuming another position If this plan be carried out, there will be no additional fatigue to the patient from the application of the stethoscope By its use we may learn more of the real strength of the heart than the pulse or the heart sounds could give us, and we may get an earlier warning of the necessity for increased efforts to sustain the heart's action

Antipyretic measures undoubtedly decrease the frequency and severity of pulmonary complications Liebermeister reports concerning 1743 typhoid patients, about one half of whom were treated by cold baths, that the number of cases of pulmonary consolidation was reduced from 14 4 per cent to 10 9 per cent, and that the mortality of these cases was reduced from 54 per cent to 34 per cent

PENETRATING WOUNDS OF THE ABDOMINAL CAVITY[3]

BY S M HAMILTON, M D,

OF MONMOUTH ILL

Penetrating wounds of the abdominal cavity, with injury to any one of the contained viscera, may be considered if not necessarily fatal, yet always doubtful of favorable termination under any course of treatment. The probabilities of not one, but several of the abdominal organs being implicated in the injury, the danger from surgical shock, concealed hæmorrhage, and local or general peritonitis, are considerations of extreme gravity. This paper is intended to be more suggestive than discursive, and will be confined to a single division of the subject, namely, the management of wounds of the intestine, lacerated or incised, from missile, or pointed instrument, penetrating or traversing the abdominal cavity.

[3] Read before the Military Tract Medical Society Nov 10 1885

Until a very recent period the history of these cases is a chapter of dismal failures. A minute analysis of the literature of the subject would be full of instruction and interest, but it is too extensive for a paper like this, and the records are open and familiar to all. It is only within a very few years that anything better than the expectant and palliative treatment in these cases has been attempted. It is true that Larrey and some of his cotemporaries made some attempts at surgical interference, but so far as the records show, the enlargement of the external wound was confined to barely as much as was necessary to find, and close with suture, a wound in the intestine, whilst no mention is made of that more important procedure (without which all else will be vain), the thorough cleansing of the peritoneal sac of all blood clots and irritating material which, in almost all cases, escape from the wounded gut.

The surgical history of the late war records about eighty per cent of deaths from this injury. In but very few cases was there any departure from the expectant and palliative plan of treatment. The tables include wounds from sabre, bayonet and bullet, and pieces of shell, the two last, of course, by far the most numerous. Of nine cases of bayonet wound, six recovered without any special surgical interference. In at least two there was room for doubt as to the fact of intestinal perforation at all. In the others, the evidence is conclusive that the gut was wounded, but under such favorable conditions that the rent was sufficiently closed on the withdrawal of the weapon to prevent fæcal infiltration, and permanently, after a spell of local inflammation. It is quite apparent in these nine cases, that the form of the weapon had a great deal to do with the favorable result. The bayonet has no cutting edge, is generally blunt-pointed, smooth and polished. A wound from it approximates that made by a trocar. The tissues are not cut, but separated, have a tendency to spring back into place on the withdrawal of the instrument, and close up the wound of entrance.

Gun shot wounds are far more likely to produce dangerous consequences. Yet it is quite possible for a bullet, even of large size, to traverse the belly from front to rear, or from side to side, without wounding the intestine, or seriously injuring any other of the important viscera. One case of this description is found in my own experience. A musket ball penetrated the abdominal wall one inch to the left of and a little above the umbilicus, passed directly through the body, and escaped at a point about one inch from the spinal column. The patient fully recovered, without any bad symptoms except those which usually attend a moderate attack of local peritonitis. There was in this case conspicuous absence of the protracted and unmanageable shock which so often attends cases of wounded intestine, but little pain, and no rapidly developed meteorism, and to confirm the correctness of the diagnosis, the patient had regular discharges of normal fæces about every second day, until his complete recovery took place. I believe it quite in the range of possibility for very small missiles, such as bird shot, to penetrate the bowel and the punctures close up at once, like the wound of the hypodermic needle or small trocar, and give but little trouble. One such case I have seen. It needed no special treatment, and fully recovered.

These rather tedious details are given to give emphasis to the doctrine that even here, in these cases of severe abdominal injury, the claims of conservative surgery are by no means to be overlooked.

The evidence of serious intestinal lesion is generally clear and conclusive. The shock is marked and profound, and disinclined to yield to treatment from the first. The small thread-like pulse, cold, clammy skin, and the shrunken hyppocratic face, show an alarming condition of nervous prostration. Very often, but not always, there is bilious or stercoracious vomiting. Always great pain, and rapidly developed meteorism. If the external wound is large, sulphuretted hydrogen, or fæcal matter, may be detected by sight or smell. Aside from this last (which is conclusive), the rapidly developed meteorism, which is always present, possesses more diagnostic value than anything else. It is of course caused by the escape of gas from the torn intestine into the peritoneal sac. These are the symptoms generally present. They are exaggerated or lessened, according to the situation and extent of the internal injury. They seem to be plain and conclusive, and easily understood *on paper*, but I presume that in many of the cases there is a wide margin for mistakes in diagnosis, mistakes which, on the one side, may subject the patient to a needless and dangerous operation, and on the other side, cut him off from his only hope of safety. I know of no situation in which a surgeon may be placed, where rapid and correct deductions, from symptoms to conditions, are so necessary as in these cases of penetrating wounds of the belly. What is the matter? is the all important question, and there is but little time which can safely be given for its solution.

For obvious reasons, wounds of the small intestine are much more dangerous than those of the large. A missile traversing that part of the cavity almost certainly will cut across not one, but several, folds of the gut, making not one, but many wounds by which poisonous gas and fæcal matter are poured out upon the sensitive peritoneum. Added to this is its greater mobility from outside disturbance and peristaltic action, lessening thus the chances of cure by adhesive inflammation between the folds of the peritoneum. Wounds of the large intestine are less dangerous because it is in some degree a fixture in the abdominal cavity, is less dislocated or disturbed by peristaltic action, and a part of it is not covered by peritoneum A wound involving this uncovered portion of the large intestine alone, should have less of the dangerous element in it than the same amount of injury to any other part of the intestinal tube

The general indications for treatment of these cases are so plain that no one need err Perfect rest, abstinence from food for several days, stimulation until reaction takes place, and *opium* from the first hour should be given freely, to quiet the peristaltic action of the bowel, and keep the irritable nervous system in subjection This last is of vital importance in all cases of abdominal injury, when peritonitis, local or general, is to be expected, whilst in cases of intestinal lesion it allays the terrible pain and prevents, to some extent, the pouring out of gas and fæcal matter into the peritoneal cavity, by its power over the muscular fibre of the bowel The constitutional effect of mercury would seem to be indicated in cases of this kind where a high grade of peritoneal inflammation is expected Its purgative action should be carefully guarded by a sufficient amount of opium, and the remedy stopped as soon as the mercurial fœtor of the breath is noticed

The main object of this paper is to call attention to the surgical treatment of certain cases of abdominal injury which, if left to themselves, almost without exception terminate fatally I refer to cases of gunshot wounds involving one or more folds of the, intestine The cases are as desperate as can well be imagined, and if let alone, or subjected to general treatment alone, there is nothing in prospect for them but a speedy and grievously painful death The surgical expedients carried out by Larrey and others were attended with little success They seemed to have a great fear of wounding and exposing the peritoneum, and contented themselves with as little enlargement of the external wound as was necessary to reach and close the wound in the intestines It is only recently that surgeons have learned that the peritoneal membrane is but little more susceptible of inflammatory destruction than other parts of the human anatomy The modern operation of ovariotomy teaches us that the abdominal cavity may be laid open from ensiform cartilage to pubes, its contents exposed to the atmosphere for hours, and the peritoneum cut and torn very extensively, without the occurrence of fatal traumatic peritonitis The earlier operators for ovarian disease urged as a reason for surgical interference that the disease if left to itself or subjected to any other treatment known to the profession, was necessarily fatal, sooner or later It was a good philosophical reason for a bold and hazardous experiment, and probably, outside of such a consideration, no surgeon would have had the hardihood to undertake such an operation The beneficent result is, that now more than seventy-five per cent of these necessarily fatal cases of disease are completely and permanently cured The same reason for operative procedure is good in these cases of wounded intestine Absolutely nothing but death can be expected, preceded by many hours or days of unspeakable agony

In looking over the literature of the cases in which laparotomy has been resorted to, even those lately performed, one fact seems very prominent, that the old fear of peritoneal injury still sticks in the minds of some operators, and stands in the way of that carefulness of detail and thoroughness which alone can secure and deserve success The last case I have seen reported is one by Dr Parke, of Chicago, the unfavorable result of which was no doubt owing to some blood clots, partly disorganized, found in the peritoneal cavity They had no doubt been overlooked in the dressing The thorough exploration of the cavity was rendered difficult, or impossible, by the faulty primary incision, made through the track of the ball, far over to the left side, instead of in the linea alba The incision should be central without reference to the external wound, and large enough to expose the entire cavity to the closest inspection, so that every wound shall be discovered and secured by stitch or suture, all hæmorrhage controlled, and above all, a thorough cleansing of the peritoneal sac from blood clots and any liquid or solid foreign material which may have escaped from the intestinal canal

If any one imagines that this is not a tedious and difficult operation, it is my opinion that his first case will afford him a rude awakening from a foolish dream I am told that it is not always an easy matter to find these wounds, especially of the small intestine, and still oftener is it difficult to isolate them, so that they may be properly closed Then there are the different kinds and sizes of solution of continuity, from complete division, requiring invagination of the gut, to the small puncture, requiring but a single ligature, all taxing to their utmost the skill, patience and the ingenuity of the operator Nothing should be neglected, be the time long or short Everything for the safety of the patient should be done in the most thorough manner possible under the circumstances

I believe that any and every form of stitch or ligature known to the dressmaker or the surgeon may be needed in these cases The glover's stitch, the basting stitch, the interrupted suture, and the simple ligature, all may have their uses according to the kind, shape, and extent of the injury to be repaired Operators have used iron wire, silver wire, catgut, animal tendon, and I know not what else, for this purpose But I believe most operators have gone back to good old-fashioned silk And why not? It is animal fibre, in as minute division as anything known consistent with the necessary strength I believe that experience proves it as good as the best for closing these and all other kinds of wounds Post mortem evidence is conclusive that the heavy silk, stump ligature, used in ovariotomy, and dropped into the peritoneal cavity, disappears so entirely within a year, that not a shred of it can be found

I hardly know what to say about "Listerism" in connection with laparotomy for wounded intestine I believe *the spray* is mostly abandoned Many consider it an agent of evil, rather than good We all use a weak solution of carbolic acid to bathe hands and sponges and instruments Is it merely a habit, a "fashion," as much honored in the breach as the observance? In my opinion the largest logic which can be extracted from the "noisy pother" of Mr Lister and his enthusiastic admirers is, that extreme cleanliness and good ventilation are the chief factors in the equation of successful surgery

The success which has already attended some of our surgeons in the very worst cases of wounded intestine, should give us hope for better things to come Dr Bull, of New York, reports a case with seven perforations of the gut, and Dr J B Hamilton another with eleven perforations, both treated by laparotomy, and both made complete recoveries

The subject should surely enlist in its investigation the best thought and the best work of the profession

---

THE ETIOLOGY OF RACHITIS[1]

BY H C HAVEN, M D,

OF BOSTON

Although we can hardly accept Jenner's statement that rachitis is the most common, the most important, and in its effects the most fatal of the diseases affecting children, as holding true in this country, it is yet sufficiently common to make its prevention of great importance to the public health It is, typically, a preventable disease—so far as serious results to the individual are concerned—if proper treatment is instituted early enough It might, probably, be absolutely prevented, if we knew the ultimate causes

My purpose is to briefly present the statistics I have gathered as to the effect of the commonly accepted causes of rachitis on its production in this city

During the past three years, at the West End Dispensary for Children, there were in attendance—

Total number under 7 years	1,516
' " of rachitics	75
Percentage of rachitics	4 94
Total number of colored under 7 years	90
rachitics	38
Percentage of colored rachitics	42 79
Total number of foreign ancestry under 7 years	340
" ' ' rachitics	20
Percentage of rachitics of foreign ancestry	5 88
Total number American ancestry under 7 years	114
' ' ' " rachitics	4
Percentage of rachitics of American ancestry	3 50
Number of ancestry unknown	973
' " " rachitics	10

RACE

Classifying the rachitics as to race, we find, of the number where it is known Colored, thirty-eight, foreign, twenty, American, four Of the twenty rachitics of foreign ancestry (Provinces included), there were Portuguese, three, Italian, two, Irish, two, English, two, French, one, Nova Scotian, two, Russian, one, German, one, of mixed parentage, both foreign, four, of mixed parentage, father American, two, of mixed parentage, mother American, one

FEEDING

Breast alone till 3 months,	308	11	rachitics or	3 57	per cent
" ' ' 6	295	7		2 37	per cent
' " ' 9	137	10	'	7 29	per cent
' 12	200	7	'	3 50	per cent
' ' over 1 year	60	3		5 00	per cent
Breast with other food till 3 months	74	5	rachitics or	6 75	per cent
" 6 '	43	2		4 65	per cent
" ' ' 9 '	83	3		3 66	per cent
' " " 12 '	477	9		1 04	per cent
over 1 yr ,	381	17	or	4 46	per cent
Artificial feeding only	119	13	rachitics or	10 85	per cent
Number where food not known				286	
' ' and rachitic				3	

These figures need, of course, a further analysis to make them of much value, but they show, I think, very clearly, that other factors than food are, in this series of cases, the original or exciting causes of rickets

Having noticed the frequency of rachitis among the colored in this series—and I have observed this in the attendance at other dispensaries—let us analyze the feeding of the colored children to see if, so far as they are concerned, the dietetic factor is an important one This was as follows

Breast without other food till 3 mos ,	18	7	rachitics or	38 88	per cent
' ' 6 '	8	3	'	37 50	per cent
' " ' " 9 "	5	4	'	80 00	per cent
' " ' 12 '	9	4	'	44 44	per cent.
Breast with other food till 3 mos	7	1	rachitic, or	14 28	per cent
' 6	4	1		25 00	per cent
" " 9 '	3	1		33 33	per cent
' " 12 '	16	8		50 00	per cent
' ' ' over 1 year,	27	12		44 44	per cent.
Artificial feeding only	16	6	rachitics or	37 50	per cent.

I recognize the objection, that these statistics are too small to have great weight, but I cannot but think they are sufficiently numerous to show that at least the dietetic factor is not an important one in producing rickets in colored children in Boston, the per cent of all rachitics among all colored is only a little less than the per cent of colored rachitics in the artificially fed from birth And in this series of cases, moreover, many colored children are not counted as rachitic where they only showed slight bone changes Since December 1, 1884, about the time I began to carefully note any evidence of rickets, the total number in attendance under 7 years has been 495, and fifty-two colored, or 11 5 per cent

Of the fifty-two colored, twenty-five only were non-rachitic, and twenty-seven rachitic, 51 9 This per cent even is too small, however, I am very sure as sometimes, in the hurry of examination, I have neglected any record as some of my charts remind me The only question in regard to the dietetic factor yet to be spoken of, is this Is the milk of colored mothers, otherwise healthy, as good an article of diet as the milk of the other races? I have no reason to doubt it or affirm it, except that in many of the cases there is no evident failure of nutrition on the part of the child I hope later to present some analysis of the milk of women nursing rachitic children

Assuming, then, the preponderance of rachitis among the colored race in Boston, and granting the effect of the diet they receive not to be a marked one, at least, as I think we are justified in doing, the question arises as to what other cause may be acting, peculiar not to any racial dyscrasia, but resulting from racial or acquired character and habits, that is, are the quarters of the city in which they live more densely crowded, are the tenements they inhabit more damp and cold or having less sunlight, are their habits of caring for their children, especially as to taking them out of doors, different from those of the equally destitute of other nationalities? I can only give my opinion, that all these questions must be answered in the negative I have no positive information, and hope I may obtain some from others to night My experience has been, that the colored are more lavish in expenditure for food and rent than other poor, taken as a class, that in equal ways their table is better equipped and the food better cooked As for the airing of the children, I do not see how they could be taken out *less* than the children of the Irish poor, until after they can walk, after that time I have noticed no difference

---

[1] Read before the Section for Clinical Medicine Pathology and Hygiene, of the Suffolk District Medical Society December 9 1885

Another question must be considered Are one or both of the parents less healthy than the average white of same social condition? If they are, this may be considered as a causative influence, transmitted but not acting through direct heredity

Of the 33 colored rachitics whose family history is known, both parents *said* to be healthy in 21

Mother healthy in 4 cases, father dead in 3, 1 Bright's, 1 phthisis, 1 rheumatism, in one father had cough every winter, well in summer

Father healthy in 5, mother dead in one of phthisis, "never strong in 2," married at 13 in 1, rheumatic in 1

In 2 cases there was phthisis in father and asthma and rheumatism respectively in mother, in 1 father had phthisis and mother died in confinement

Of 31 rachitic white, whose family history was known, parents said to be healthy in 23

Of the 8 remaining, in 3 father healthy, mother had chorea, rheumatism and measles at birth of child respectively

Mother healthy in 3, father, kidney disease, arsenical poisoning, and "not strong"

Mother dead of phthisis in one, with father not strong, father rheumatic in one, mother healthy excepting catarrh which had destroyed septum, specific

No history of syphilis in any, nor have I seen any rachitic symptoms in a number of confessedly syphilitic children

In this comparison we see not much difference, but of course the statements of the parents are of comparatively little value, I think undoubtedly, in this climate the average of health is less in the negro than the white native or immigrant from the north of Europe How much lower, if any, it is than that of the immigrant from France or Italy, I have no means of forming an intelligent opinion

In any case I do not believe there is enough difference to account for the marked preponderance of rickets on the ground of the parents' health, though it may, and undoubtedly does, exert an influence

What, then, is the determining cause of this frequency? I see no source of any such cause but what must arise from a peculiar predisposition to this form of disease in the colored Is this to be referred to anatomical basis, as, for instance, are the arteries of this race larger or wider? I know of no such peculiarity And again, if the statements made to me by lay observers are true, that the disease is the less common the farther south we go, that would preclude any such hypothesis being entertained I can find no medical testimony as to its relative frequency It is stated, however, to be practically unknown in tropical regions In the writings on African explorations, I have met no notice of such a disease having been noticed among the young, as it would probably have been had it existed Again, I have been told by lay observers that the disease is the more frequent and severe, the purer is the African blood, and I have found this to be true in my experience in this city

The only hypothesis I can suggest to myself to account for the relative frequency of rachitics in the colored race is that as their natural habitation is much farther south than North America, the effect of the climatic conditions, which are recognized as having a causative effect in rachitics, is exaggerated, the purer the African blood the more will the effect be noticed In other words, there is an inherited necessity for heat and sun which our climate does not satisfy, and rickets results It is striking in this connection to notice that of the white rachitics of a foreign ancestry, the majority are born of parents coming from the south of Europe, where the disease is relatively rare, rather than of parents from England and North Germany, where the disease is rife

I have presented these facts principally for the purpose and in the hope of eliciting criticism and information which shall enable me the better to make a more thorough study of the subject than I have had the time to do in this sketch

MEDICAL PROGRESS.

SUPPURATION AROUND THE VERMIFORM APPENDIX TREATED BY ABDOMINAL INCISION —At the meeting of the Clinical Society of London, on December 11, 1885, DR THOMAS BARLOW and MR RICKMAN J GODLEE read a paper relating to a man, æt 20, whose previous history was unimportant, except that for the last two years he had been subject to attacks of diarrhœa and vomiting His illness began rather acutely on September 12, 1885, with loss of appetite, severe abdominal pain, and later, vomiting and absolute constipation He was admitted into University College Hospital on the 15th, with a temperature of 102 4°, intense abdominal pain and tenderness, intermittent bilious (not stercoraceous) vomiting, and tight distension of the abdomen There was a small patch of slight redness in the right iliac fossa The diagnosis appeared to be between mischief about the appendix and constriction of the intestine by a band high up He was given opium and iced beef-tea, and ice was applied to the abdomen The temperature fell to normal, and the pulse was about 90, full and soft, the tongue dry and the color good, but, as the symptoms were unrelieved, an exploratory incision was made in the middle line on the night of the 16th General early peritonitis was found, but lymph only in the neighborhood of the cæcum, surrounding a collection of fetid pus The vermiform appendix was much thickened A second incision was made over the right iliac fossa, and a large drainage tube was inserted through it, reaching down to the appendix, a smaller one being placed in the median incision, which was closed with sutures The peritoneum was first washed out with a solution of corrosive sublimate (1 to 500) The patient made an excellent recovery, the temperature remaining normal, and the pulse about 90 He was fed principally by the bowel for some time, beef-tea and arrowroot were allowed on the twentieth day, and minced meat a fortnight later No drugs were given except morphia for the first two days Thirst was allayed by means of warm-water enemata He had slight albuminuria a day or two after the operation, and a little later a parotid bubo occurred which did not suppurate It was claimed that the uncertainty of the diagnosis justified the exploration, and that the early evacuation of the putrid pus rescued the patient from a condition of very great danger and prevented the matting together of the intestines which would otherwise have occurred The freedom with which the peritoneum might be treated was pointed out, and the advisability of withholding food from the stomach for a prolonged period in such cases was insisted upon Remarks were also made upon the absence of peritonitis and the presence of albuminuria as points in the diagnosis, and upon the relation between inflammation of the parotid and diseased states of the peritoneum

Mr Morrant Baker related a case under his own care, in which an abscess in the neighborhood of the cæcum had been evacuated by operation, but which had recurred with a fatal issue at a later date, the cause being found in the presence of a needle projecting through the vermiform appendix and held in its position by hard concretions on the inner side, thus forming a permanent source of irritation

The President described a case in which, with all the signs and symptoms of peritonitis, an abscess was discovered and evacuated through a lumbar incision with perfect success Acute peritonitis was rare without a local cause, and this was very frequently to be found about the cæcum He suggested that exploratory incisions should always be made in that region Mr Baker's case was remarkable as proving beyond all doubt that foreign bodies might sometimes lodge in the vermiform appendix, a possibility which had been denied on the highest authority

Mr C J Symonds remarked upon the fact that in Mr Godlee's case the escape of the pus into the peritoneal cavity had not prevented the success of the operation Such a fact was very encouraging, and would lead to more active treatment in this class of cases, which were sometimes impossible to diagnose The ordinary signs and symptoms were not always sufficient to indicate the nature of the attacks of intestinal obstruction or peritonitis which appeared at times to come on absolutely suddenly There could be no doubt that foreign bodies in the vermiform appendix were very rare

Mr Barker considered that more decided action would in future be taken in dealing with these cases He related the particulars of a case in which he had operated for the relief of strangulation by volvulus in the presence of acute general peritonitis Although the coils of intestine were in places matted together with lymph, he had been able to search the greater part of the course of the small intestine and also the cæcum, to wash out the cavity and the coils of intestine, and to return them without difficulty and with perfect success The case had done well since the operation He thought that such a case, with others similar to it which were now accumulating, proved that the inflamed sac of the peritoneum might be dealt with in the same way as that of an ordinary abscess

Dr Barlow confessed to a feeling of relief that no adverse criticism had been advanced to the early surgical interference in this case He was aware that many physicians of experience were not in favor of it The result of the case had been perfectly satisfactory, and the patient had recovered without any of that thickening round the wound which was apt to become a source of future danger The really important element of the case, after the operation, was the feeding The abdomen had to be kept at absolute rest, and hence nutrient enemata had been employed The rectum, however, was not usually tolerant of ordinary enemata after the first day or two, and hence arose a serious difficulty which was only partly to be overcome by the use of peptonized meat extract and peptonized milk Thirst was almost always a serious feature in these cases, the mouth and tongue often getting very dry and coated By giving the tongue something to do, however, this difficulty could be got over, and in this case, by causing the patient to chew the meat without swallowing it, the desired result had been obtained

Mr R J Godlee observed that he should bear in mind the remarks of the President with respect to making exploratory incisions in the neighborhood of the cæcum He related his own personal experience to the effect that the pain in inflammatory affections of the cæcum is often felt on the left side of the abdomen He thought that the patients' own history of very sudden onset of the attack was not always trustworthy—*Medical Times and Gazette*, December 19, 1885

Extra-Peritoneal Incision of a Small Pelvic Abscess —At the meeting of the Obstetrical Society of New York, on November 17, Dr W M Polk related this case Two months before a woman had entered his service at Bellevue Hospital with a pelvic abscess, which pointed in the posterior cul-de-sac He opened and drained the abscess per vaginam, but, although the patient at first improved, she began to have hectic, and speedily lapsed into a condition resembling the last stage of phthisis Thinking that there was another accumulation of pus which had not been reached, the speaker introduced his finger into the abscess and explored it thoroughly, but could detect nothing After waiting two weeks longer, the patient was anæsthetized, and a thorough examination was made With a finger in the abscess cavity, one in the vagina, and another in the rectum, a suspiciously soft, but not fluctuating mass, about the size of a pigeon's egg, could be felt behind the left broad ligament, between it and the rectum, and apparently attached to the pelvic wall just above the spine of the ischium There was no pointing or even bulging in the direction of either the rectum or the vagina The problem was how to reach it To go down through the cavity of the abdomen, meant that the pus would have free access to the peritoneum, as from the position of the supposed abscess and its size, its walls could not be attached to the abdominal opening so as to drain its cavity, and at the same time exclude its contents from the abdominal cavity The enucleation of the entire abscess contents and walls seemed too serious an undertaking in the patient's weakened state, so the idea of reaching the mass by laparotomy was abandoned The next suggestion was naturally that an attempt should be made to reach the pus through the vagina, or rectum, or old abscess cavity Its remoteness from the walls of all these cavities, the number of the vessels in the involved region, with the presence of the ureter, made him hesitate to attempt evacuation through either of these cavities There remained but one other path, and that was outside the peritoneal cavity, by going down between that cavity and the pelvic wall The incision for ligating the common iliac artery was made, the peritoneum was easily pushed back until the brim of the pelvis was reached, then the index finger was carefully and *easily* worked down along the pelvic wall toward the abscess until the resistance to further progress showed that he had reached the region of adhesions usually surrounding such spots, gently forcing the finger onward, the abscess cavity was reached, and about one ounce of fetid pus was evacuated A drainage tube was put in and the cavity cleansed This cleansing has been done twice daily, and to date the patient has been well It was three weeks since the operation

DR JANVRIN had never seen a parallel case He thought that Dr Polk was most fortunate in being able to detach, and afterwards to open the peritoneum, because it was generally thickened and adherent in such cases

DR WYLIE said that he had frequently removed by laparotomy abscesses connected with the tubes and ovaries He washed out the cavity afterwards with a solution of carbolic acid, 1 to 100, or of corrosive sublimate, 1 to 10,000, and afterwards with water which had been purified by boiling He thought that the tubes were generally the centres of suppuration

THE PRESIDENT asked if the speaker would open and drain a *pelvic* abscess through an abdominal-peritoneal incision

DR WYLIE replied that he would drain such an abscess through the vagina if it could be reached, but that if is reformed, it was probable due to pyosalpinx, and hence laparotomy was necessary

DR BYRNE asked Dr Polk if he had ever had any trouble from secondary hæmorrhage [Dr Polk replied that he had on two occasions] DR BYRNE said that he had frequently opened pelvic abscesses through the vagina, and even through the rectum, but that he had never seen any hæmorrhage He thought that the surgeon should hesitate for a long time before undertaking such an operation as that just reported It was not only difficult to separate the peritoneum in the manner described, but that delicate membrane would certainly be injured during the operation

DR SKENE asked if pelvic abscesses were not frequently followed or accompanied by cellulitis

DR POLK replied that his experience had led him to believe that pelvic cellulitis in the non-parturient uterus was a rare condition

DR SKENE believed that he could generally do better by aspirating pelvic abscesses through the vaginal roof, and then washing out the sac by simply reversing the current

DR POLK agreed with the speaker, but thought that aspiration was merely a temporary expedient, which should be followed up by the radical operation

DR SKENE thought that the needle could be left *in situ*, and a fine thermo cautery knife could be passed along it as a director, the abscess being thus opened with much less risk of hæmorrhage and subsequent inflammation

DR POLK said that he would have been afraid to use a cautery in his case on account of the close proximity of important structures, especially the ureter He remarked, in conclusion, that it would have been impossible to open the abscess by laparotomy, and since it did not point, and could not be reached through the vagina, there was only the one other alternative which he had adopted If he had another similar case, he thought that he would perform the same operation, as no difficulty was met in separating the peritoneum, and that membrane, as was well known, did not seriously resent that proceeding —*Am Jour of Obstetrics*, January, 1886

PARTIAL DISLOCATION OF THE HEAD OF THE RADIUS PECULIAR TO CHILDREN —MR SIDNEY H LINDEMAN, in a short paper on this subject, says that the late Mr McNab, of Epping, was the first to call attention to this injury in England, in Heath's "Junior Surgery," and in Ranking's *Abstract* for 1863, vol 1, there is a paper by Dr Hodges on the subject M Goyrand has also paid it much attention But great doubt has always been expressed as to whether this injury in children under 5 years of age, is a dislocation of the radius at the elbow, or a displacement of the fibro cartilage at the wrist, so difficult is it in children of this early age to get a complete diagnosis The dislocation has in every case that I have seen, occurred in children under the age of 5, the most common period being between nine months and two years It is a partial dislocation of the head of the radius, forwards on to the condyle of the humerus, perhaps in some cases reaching the shallow depression above the trochlear surface which goes by the name of the radial depression It is generally caused by some one saving the child from falling by taking hold of the hand In elder children, it is caused by nurses swinging them around by the hands, or it may result from a fall In the first two cases, the tendon of the biceps largely participates in its production This muscle acts both as a supinator and a flexor of the forearm, but it also flexes the arm on the forearm, when the latter is fixed, as in climbing, and, consequently, any great traction at the wrist causes it to be strongly brought into play, and so tends, by reason of its attachment to the posterior surface of the tuberosity of the radius, to bring the upper extremity of that bone forwards, out of its place (In adult life, I doubt if this partial dislocation ever occurs, but several cases are reported of complete dislocation forwards *Vide* Dr Will, *Lancet*, June 7, 1879)

After meeting with the accident, the child is brought evidently in great pain The injured limb hangs down midway between pronation and supination The person who brings the child rarely knows where the injury lies, but generally thinks it is in the shoulder Taking hold of the hand causes very great pain The elbow is found to be hotter than its fellow, and there can always be felt an unnatural prominence on the outer side of the joint Flexing the arm to a right angle and complete pronation can be accomplished, but, in attempting to flex more, or to supinate, some resistance is felt

Reduction of the dislocation is accomplished by taking the hand of the child in the opposite one and strongly supinating, at the same time that the thumb of the other hand presses on the head of the radius Before complete supination has taken place, a distinct "thud" will be heard, and the head of the radius felt to slip back One of the peculiarities of these cases is, that the child, a few minutes after the reduction, will move the hand and arm, and will even grasp anything that may be offered to it, without apparently suffering any pain These dislocations have a great tendency to recur, especially if not reduced early in the first instance I have seen more than one case in which permanent enlargement of the elbow joint has resulted, through the dislocation not having been diagnosed and properly treated in the first instance After the reduction, it is necessary for the joint to be kept at rest by a rectangular splint, the small tin ones being the most suitable for the purpose The injury most frequently occurs in children of the strumous type, with large ends to the bones Previously to the last two years, no notes were taken of cases seen Since doing so, twenty-four examples have come under my observation

I think that a slipped tendon of the wrist, to which children are rather liable, may have been mistaken for a dislocation, and so led to the confusion, which has previously occurred, concerning injuries to the fore arm in children of this age —*British Medical Journal*, Dec 5, 1885

MEASUREMENT OF RED BLOOD CORPUSCLES —In the *Chicago Legal News*, of July, 1885, DR MARSHALL D EWELL records some careful examinations of red corpuscles with a view to obtaining an average, more especially for medico legal purposes

An examination of the figures shows that the difference between the greatest and smallest averages of 25 corpuscles is 000028 or 1-35714 inch, a magnitude that may be easily measured by any person having the requisite skill and apparatus The difference between the highest and lowest averages of 50 corpuscles is 000015 or 1 66666 inch, which approaches more nearly the limit of micrometric measurement, though probably not beyond it The difference between the highest and lowest averages of 75 corpuscles is 000012 or 1-83333 inch, which approximates the limit of micrometric measurement The difference between the highest and lowest averages of 100 corpuscles is 000009 or 1 111111 inch, which is within the limits of personal and instrumental error, according to the highest living authority upon this subject, who writes, in substance, that it is easy to measure 1-50000 inch, but to be sure of 1-100000 inch, is not possible

The conclusion to be deduced from the above figures is obviously that, when a sufficient number of corpuscles are measured, there appears to be an average size which varies within very narrow limits, which may possibly be accounted for or at least is consistent with personal and instrumental errors, for though he has carried out the figures to the sixth decimal place, he has not the presumption to declare that the results can be relied upon farther than the fifth place, and have carried out the figures to the sixth only to insure accuracy in the fifth so far as possible Another conclusion is, that granting for the moment that it is possible to identify blood by measurements of the red corpuscles, of which he is by no means satisfied, it is reckless in the last degree, if not criminal, to express an opinion upon the measurement of less than 100 corpuscles To express an opinion upon the measurement of only 10 corpuscles—as he is informed has been done in this section within the last year or two—to take the most charitable view of the subject, betrays such culpable ignorance of a subject involving such momentous consequences as ought forever to invalidate the testimony of one who should swear so recklessly In a case involving the issue of life and death it would be better to measure several hundred corpuscles

An examination of the unabridged table of measurements, from which the above summary is tabulated, discloses the further fact that by selecting the corpuscles it would be possible for a dishonest observer to make the average much larger or smaller than that above given, without the possibility of detection, a fact, the bearing of which upon the value of expert testimony upon this subject is so obvious as to need no comment

It will be seen that he has not attempted to draw any inference as to the cause of the larger average size of the corpuscles first measured Whether it was or not due to the drugs exhibited during the beginning of this work, is an interesting subject of inquiry, which must be reserved for future examination

EXTENSIVE ACNE VULGARIS, WITH INFLAMMATORY PAPILLOMA —DR C SCHADECK, of Kew, reports the case of a man, 23 years old, who was the subject of these affections His internal organs were sound, his skin and visible mucous membranes pale On the buttocks was a large collection of acne vulgaris, in different stages of development The head, face, neck, palm of the hand, soles of the feet, internal surface of the thighs, and the axilla were free of acne On the chest and back, besides the comedones (without inflammatory appearances) were inflammatory nodules, nodes and pustules (of acne) from which exuded on pressure the contents of the fat cutaneous glands mixed with pus and some dark venous blood It was evident that some of the larger nodes were due to the confluence of several small ones, and contained a gritty material (atheroma)

Besides these nodes and pustules there were found on the chest and back a large number of round, white scars On the skin of the lower portion of the abdomen and the groins, as well as on the skin of the nates and the sides of the body, there were scattered large, oval, irregularly formed infiltrates of a dark color, formed by the confluence of several inflamed acne nodes On the upper surface of the infiltrates were numerous punctiform openings, from which pus, blood and gland contents exuded on pressure Small infiltrates were numerous on the internal surface of the forearm, and the thigh and leg The infiltrated spots on the lower extremities had the following peculiarities they had the appearance of sharply outlined, flat, oval nodes and *plaques* about the size of a silver five cent piece to that of a copper cent, the upper surface being only slightly raised above the level of the skin, but they were deep seated, and covered with small brown specks, after removal there was a red, uneven, cribriform surface Most of the pin like openings were filled with a thick purulent material, removable by pressure In a few places the surface of the infiltrates was formed of new, soft cicatricial tissue Isolated infiltrates were surrounded by a dark-red region, and showed on the upper surface wart-like growths and cicatricial changes, and were probably due to a simple closure of the glands by an inflammatory process of the skin of the surrounding region, followed by hyperplasia of the stratum Malpighi, giving rise to wart-like growths (perifolliculitis, papilloma) The apices of the papillomatous growths were grown together, and between them were a few small abscesses

The treatment consisted of potash baths, with mercurial plasters to the larger infiltrates, some of these being incised and pressed Under this treatment most of the papillomatous infiltrates were absorbed within a month and a half, and the nodes and plaques were atrophied In five months the patient left the hospital cured —*St Petersb medicinische Wochenschrift*, No 50, 1885

STRETCHING THE SUPRA TROCHLEAR NERVE IN GLAUCOMA —DR BRAILEY read a paper on this subject at the late annual meeting of the British Medical Association Badal introduced the operation, in 1882, for ciliary neuralgia, and he thought that it might give good results in certain forms of glaucoma, and in sympathetic ophthalmia Abadie stretched it in a case of glaucoma, in which the eye continued hard and painful after sclerotomy and iridectomy He stretched the nerve until it ruptured, and then removed a piece of it one cm long Tension sank in three days to normal, vision slowly and slightly improved, and the pain was relieved He has since then reported cases where stretching was advantageously combined with iridectomy or sclerotomy, even in such an unpromising disease as congenital hydrophthalmos But he expressly states that he does not think nerve stretching can yet supplant iridectomy or sclerotomy, it should be reserved for intractable cases which have resisted all other measures He suggests its probable utility in congenital hydrophthalmos, and also in glaucoma in children secondary to anterior synechia, on the ground that the loss of the eye is due to continuous traction on the nerves entangled in the scar In glaucoma, he combines it with simultaneous sclerotomy Brailey has tested the efficiency of the operation to relieve ciliary neuralgia and to lower tension in six cases In one case he stretched the supra-orbital nerve also to compare the effect He reports the following cases

1 A man, aged 49, glaucoma, the result of iritis following a cataract extraction five years ago Tension slightly in excess a month after extraction, but for five weeks had been much heightened, and vision failed rapidly Supra-trochlear nerve stretched to rupture, and four mm excised In three days tension had fallen from +2 to +½, and in six days was normal Vision slightly improved Pain wholly relieved

2 A man, aged 67, *glaucoma absolutum* of right eye Tension +3, perception of light Sight lost gradually twenty years before, considerable pain Supra-trochlear nerve stretched Considerable suppuration of wound Tension gradually fell, and ten days later, was not more than +1 Pain entirely relieved, and had not recurred after some months

3 Woman, aged 41 Double iridectomy for glaucoma three years ago Still some tension in each eye, with continuous pain over left brow Eserine gave no relief Both supra trochlear nerves stretched Wounds healed rapidly Tension fell to full in right eye, and normal in left Pain entirely ceased for a month, then both pain and tension recurred, but neither symptom quite so acute as before Vision remained the same, $\frac{6}{60}$ right, $\frac{6}{24}$ left

4 Woman, aged 63 Left, absolute glaucoma, tension +3 vision nil, some pain, right, tension +3, vision $\frac{6}{12}$, inflammatory symptoms slight Stretching of both supra-trochlear and supra orbital nerves No relief of pain, though tension fell to +1 Subsequent sclerotomy, and then iridectomy right, with result that vision remained $\frac{6}{12}$, although tension continued +1 The other eye remained as hard as ever, and was finally enucleated

5 Man, aged 75, absolute glaucoma of left eye, with severe pain Stretching of supra-trochlear relieved pain much, but in five days it returned almost as bad as before Eye enucleated

6 Woman, aged 55, severe choroido cyclitis of both eyes As a last resort, the nerve was stretched on each side Pain was diminished for a time, but inflammatory attacks soon recurred

Brailey states that he intends, in future, to restrict the operation to diseases in which, on the strength of these cases, there is good ground to expect benefit, in the neuralgia of glaucoma absolutum, and in intractable cases of glaucoma generally He is satisfied that stretching the *supra orbital* nerves has no beneficial effect on the tension, and only doubtful, at best, on the neuralgia Stretching of the supra-trochlear, he believes, does have some influence on the tension, but it is not worth counting on, in this respect, as a remedy for glaucoma, though it is of use as an adjunct —*British Medical Journal*, Oct 10, 1885

Albuminuria treated by Fuchsine — Mr A T Barnard reports the following case, which came under the care of Mr W Mitchell Roocroft Wm R aged 40, was admitted to the Royal Albert Edward Infirmary, Wigan, on May 8, 1885 There was extreme anasarca of the head, face, and legs and ascites, the tongue was coated, the breath very foul, and the skin hot and dry On inquiry, he said he had been working for some time in water in the pit He complained of pain in the lumbar region The urine, on examination, was of a pale straw color, and acid reaction, of specific gravity 1015, there was a slight deposit, and it became almost solid with albumen on boiling, under the microscope, granular casts were found The quantity of urine passed was three to four ounces on the day after admission The following treatment was adopted a vapor-bath was to be taken three times a week, and a drachm of compound jalap powder every second morning He was ordered ℞ Tinct digitalis mx, tinct ferri perchloridi mx, aq chloroformi ad ℥j, to be taken three times a day His diet was ordered to consist solely of skimmed milk, eight pints daily

This treatment was continued until July 16, with the exception that the jalap powder was discontinued on June 15 During this period, the ascites and anasarca diminished, the amount of urine passed daily varied between sixty and seventy ounces, the amount of albumen also varied between one half and one third

As he did not seem to improve under this treatment, a grain of fuchsine (in the form of pill made up with compound tragacanth powder and extract of gentian) was prescribed to be taken three times a day, and he was allowed ordinary diet

On July 20, the dose of the drug was increased to two grains three times a day, the amount of albumen when the fuchsine was commenced being one third, the urine containing crystals of uric acid and waxy casts The urine (owing to the drug) now assumed a pinky red color, and the fæces were also colored

In ten days, the albumen was reduced to one-sixth, and on August 13, there was a mere trace, which continued until he was discharged (at his own wish), and made an out-patient, still continuing the fuchsine, which was now reduced to three grains in the day

His urine was examined every week or ten days, and on the last three occasions there was a total absence of albumen, and nothing microscopically, the fuchsine being reduced to one grain in the day

On September 30, the patient was discharged, and intended to recommence work —*British Medical Journal*, Dec 5, 1885

Faradic Electricity in Rigidity of os Uteri during Labor —Dr Mary Putnam Jacobi reports the following interesting case

A primipara was brought during a premature labor, occurring at seven months of pregnancy, to the N Y Infirmary in a state of considerable exhaustion resulting from the prolonged labor pains The external os was tetanically rigid I did not see the patient until after she had been for some time in the hospital, and the physicians in charge, Dr Blackwell and Cushier, had used all the most usual and approved means of relaxing the rigidity of the os, but without the slightest effect Even chloroform had failed, and the increasing exhaustion of the patient rendered this method hazardous to be persisted in It seemed to me that the tetanized condition of the os, which would barely admit the tip of a finger, and resisted manual dilatation to an extraordinary degree, was precisely due to the exhaustion of the nerve force destined to the uterine fibre The tetanus would then be analogous to the intestinal cramps of lead colic, to those induced in both the rectum and the genital canal by compression of the aorta (in rabbits), or, on an even more general scale, to the universal muscular contractions of rigor mortis If this were true—and surely the clinical history of cases of rigid os uteri tends to support the hypothesis—local stimulation of the exhausted nerve fibres was indicated as the remedy A small electrode was applied to the os, and connected with a faradic battery, the other electrode being held in the patient's hand It was considered desirable to avoid passing the current through the body of the uterus, lest new contractions should be excited and struggle in vain against an impassable resistance The application was continued for fifteen minutes Immediately afterwards, and for the first time, Dr Cushier succeeded in inserting a finger into the cervical canal, and after some further effort, in gradually effecting manual dilatation and delivering the patient with the forceps

Stimulus to the nerve fibres thus seemed to have succeeded in inhibiting the spasm into which the muscular fibre had been thrown, as is habitual when left to its own irritability —*American Journal of Obstetrics*, January, 1886

The Crico-Hyoid Muscle —Mr Walsham, in an article on Anatomical Variations, published in the *St Bartholomew Hospital Reports*, vol xvii, described a crico hyoid muscle, consisting of a slip composed of two muscular bellies, intervening between three tendons It arose from the lower border of the cricoid cartilage, just external to, and to the right of, the median line, and was inserted into the lower border of the hyoid bone, near the median line The muscle was tendinous at its origin, but at the upper border of the cricoid cartilage it became muscular, and at the lower border of the thyroid it again became tendinous A second muscular portion, of about three-eighths of an inch in length, existed in the tendon, opposite the middle of the thyro hyoid membrane Dr Wenzel Gruber, of St Petersburg, recognizes the fact that Mr Walsham was really the discoverer of the crico hyoid muscle He found this muscle in a male subject, dissected in October, 1884 After a minute description of the specimen under his observation, he admits, not only that it agreed in origin, course, and insertion, with that described by Mr Walsham, but that he and the latter anatomist only have discovered a true and distinct muscle properly called by the above name Zagorsky's crico-hyoid, described in 1809, was simply a separate slip of the thyro hyoid, lying on the inner side of the main part of that muscle A true crico hyoid cannot be said to exist unless the thyro-hyoid be well developed and undivided, and the crico-thyroid also free from any anomaly —*Brit Med Journ* , Nov 28, 1885

COCAINE IN DISEASES OF THE NOSE, LARYNX AND PHARYNX —PROF SCHNITZLER gives an account of one hundred cases in which he has used cocaine in diseases of the nose, larynx, and pharynx In operations upon the tonsils, and in hyperæsthesia of the pharynx the results from its employment are satisfactory, but he does not think it especially useful in acute pharyngitis Though it gives good results in operations upon the larynx, he does not regard it as advantageous in laryngoscopic and rhinoscopic examinations The results of its use in irritative cough, laryngeal catarrh, acute and chronic, and in laryngeal tuberculosis were very favorable Glycerine is regarded by him as a useful adjuvant to formulæ containing cocaine The following is a good mixture for general use

℞ Hydrochlorate of cocaine	2–5 parts
Glycerine	20 "
Water	80 "
M	

When it is desirable that the anæsthetic effect be continued for some time, Schnitzler recommends the following

℞ Hydrochlorate of cocaine	2–5 parts
Morphine	2 "
Glycerine	
Water of each	50 "
M	

The following is recommended for insufflation

℞ Hydrochlorate of cocaine	2–5 parts
Acetate of lead	20 "
White sugar	80 '
M	

or

℞ Hydrochlorate of cocaine	2–5 parts
Subnitrate of bismuth	
White sugar of each	50 "
M	

He uses a solution of 1 to 500 for nasal injections and for inhalations —*Centrabllatt fur Chirurgie*, No 51, 1885

THE APPLICATION OF NAPHTHOL TO SOME FORMS OF CUTANEOUS DISEASE —P SOMBRET (*These de Paris*) gives the following *resume* of the advantages possessed by naphthol in the treatment of some forms of skin disease

1 The preparations are odorless, and stain neither the skin nor clothing

2 In the use of naphthol, with the precautions advised by Kaposi, there are observed neither forms of intoxication (albuminuria, coloration of the urine) nor active inflammation of the skin

3 In scabies, naphthol is an excellent parasiticide, and exercises a very beneficial effect upon the eruption due to the disease

4 In pediculosis the remedy is efficacious, and its use is free from danger and inconvenience

5 In psoriasis, no satisfactory effect has been observed

6 In prurigo (of Hebra) naphthol causes the itching to disappear rapidly, and has beneficial effect upon the eruption It, nevertheless, does not possess a curative power in this disease greater than that possessed by other remedies —*Revue des Sciences Medicales*, July, 1885

HIPPURATE OF SODA IN URIC ACID DIATHESIS —Garrod has already shown the effect produced by hippurate of soda on the decomposition of uric acid, and DR BON highly recommends it in affections characterized by an excess of uric acid The following are convenient formulæ·

℞ Hippurate of soda	grm	5
Carbonate of listeria		1 50
Glycerine		15
Distilled canella water		250
M		

Dose —15 grammes four times a day

℞ Hippurate of soda	grm	6
Chlorate of potash		1 50
Simple syrup		20
Peppermint water		200
M		

Dose —15 grammes four or six times a day

—*Nouveaux Remedes*, Jan 1, 1886

RESORCINE IN EPITHELIOMA —DR RUBINO ANTONIO reports a case in which he successfully applied resorcine to an epitheliomatous tumor, about the size of a pea, on the side of the nose of an elderly man The tumor was apparently attached to the bone, and surrounded by an area of reddened and infiltrated skin An ointment containing 15 parts of resorcine to 20 of vaseline was applied twice daily after the tumor was washed with permanganate of potash solution The discharge diminished, and the tumor grew smaller, until at the end of five months nothing was left except a small cicatrix —*Giornale Internaz delle Scien Med*, Oct, 1885

IODOFORM IN CONSUMPTION —DR VESTE, after having used iodoform in phthisis for some time in the form of inhalations, says that he has obtained very good results from it, either on the local morbid processes or on the general condition of the patients Given internally it produces no good effect and it increases the fever In apyretic and non-tuberculous cases it has caused increased destruction of nitrogenized tissues, and Veste thinks, consequently, that this accounts for the increase of the fever It does not reappear in the urine when given internally, but is thus found when used externally —*Les Nouveaux Remedes*, Jan 1, 1886

SOLVENTS OF BINIODIDE OF MERCURY —In a recent communication made to the Académie de Médicine of Brussels, M MEHU stated that castor oil is one of the most powerful solvents of the biniodide of mercury, in the proportion of grm 1 to 50 The addition of iodide of potassium adds to this solubility Lard only takes up grm 4½ to 1000, and vaseline grm 1 to 4000 Carbolic acid warmed to 212° F dissolves about grm 20 to 1000, but half of this is precipitated on cooling At ordinary temperature benzine dissolves grm 4 to 1000 —*Presse Med. Belg*, Oct 18, 1885

EXPLORATIVE LAPAROTOMY

The subject of laparotomy for diagnosis was very tersely put by Mr Lawson Tait during his recent visit to this country, when, on being asked for an opinion regarding the nature of an obscure abdominal tumor, he said "Cut the patient open and find out" And it is interesting to know that that patient was cut open, and saved by hysterectomy from almost certain death Surgeons are beginning to understand that laparotomy is not such a dreadful operation after all That it is a capital operation must be admitted, but so are many others that no surgeon hesitates to perform The idea is rapidly becoming a thing of the past that the peritoneum is a structure which must not be touched

In his Address as Chairman of the Surgical Committee of the Medical Society of the County of Kings, delivered in October, 1885, DR GEORGE R FOWLER made some most suggestive remarks on the subject of "Explorative Laparotomy" The Address was worthy a bold, skilful operator In speaking of the work done by Mr Tait and Mr Treves, he says "But there is yet room for missionary work before men, and good men too, can be induced to come out of their shell of conservatism, so called, and with a bold front help to break down the prejudices and misgivings based upon an ill-founded fear of the peritoneum and its behavior under the knife" It is not a week since a New York surgeon expressed himself as having as little fear of opening the peritoneum to day as he had of operating upon a cervix uteri five years ago Dr Fowler divides the cases calling for explorative laparotomy into four classes 1 Cases in which a diagnosis cannot be made without opening the abdomen and exposing the parts to the direct touch, or even perhaps to the sight, of the surgeon, but in which further interference is thereby shown to be impracticable or uncalled for 2 Cases in which a provisional diagnosis only can be made, unaided by abdominal incision, and in which but slight additional risk is incurred by an immediate and radically curative procedure, based upon the knowledge thus gained 3 Cases in which a diagnosis has been made, but in which doubt exists as to the practicability of performing a radical operation, and cases in which the choice of the particular operation best adapted to the individual case must be decided upon after incision and exploration 4 Cases in which the patient's life is in imminent peril, and in which it becomes imperatively necessary to at once locate the lesion threatening life, and to be prepared to act promptly upon the knowledge gained by opening the abdominal cavity

The cases to be included under the *first* class are, as said, those in which an operation would be impracticable or is uncalled for, and if any benefit is derived it is not from any design on the part of the operator It is well known that there are many cases of severe pelvic or abdominal pain in which a diagnosis is impossible without an operation, though the symptoms give a strong suspicion of chronic ovaritis or salpingitis In some cases nothing can be found by an operation to account for the pain and other symptoms, and yet they disappear promptly after the operation In this first class also may be included cases of recurring ascites in which peritoneal disease is suspected, and cases of traumatic peritonitis, "in which incision is made and drainage supplements the otherwise purely explorative operation In cases under the *second* class a partial diagnosis has been made, sufficient with the symptoms to show that the patient's life is in danger and that something must be done Here, as in cases coming under other classes, there is sufficient obscurity to make the surgeon wish—as thousands have wished—that he had his hand inside "As illustrative of this class of cases, chronic ovaritis, or salpingitis, with or without hydro or pyosalpinx, may be cited In some of these cases, although attended with considerable difficulty in making a positive diagnosis, yet the suspicion amounts almost to a certainty Here an opening sufficiently large to admit the introduction of the index finger will clear up the doubt" So also may perforations, diseased conditions of the vermiform appendix, and other affections be diagnosticated "It is no argument against explorative laparotomy in this class of cases to say that the adhesions limiting and walling in the seat of perforation and extravasation of fæcal matter would thereby be prevented from forming" These adhesions occur but rarely, and even when they are formed the patient's life is endangered by the probable rupture of the resulting abscess, and "when they do not form at once, oftentimes perforation, diffuse peritonitis, and, in consequence, certain death, is the rule" In this class of cases, predicts Dr Fowler, explorative laparotomy will be the means of saving many lives

In the *third* division Dr Fowler places cases in which a diagnosis has been made, but some doubt still exists as to the practicability of performing a radical operation In this sense he thinks that most cases of ovariotomy and hysterectomy may perhaps be looked upon as being, in some degree, explorative operations, as easily seen by the number of cases in which an operation has been commenced, but abandoned on account of the high improbability of success Hence the wisdom of always making, as our author advises, the incision as if for simple explorative purposes, when, if the operation be found impracticable, the wound to be healed is not so large "Explorative laparotomy will also prove useful in cases in which chronic intestinal obstruction may occur, and the question may arise regarding the propriety of attempting to relieve the obstruction after determining its location and nature Resections of a portion of the gut or of the pyloric extremity of the stomach in stenosis at that point are instances in illustration Cases of uterine fibroma of small or medium size, which, because of exhausting hæmorrhage, demand interference, will require a preliminary explorative operation before a choice can be made between simple removal of the appendages or a hysterectomy" Of course in the greater number of cases removal of the appendages is sufficient and perfectly practicable, but now and then a case is met with in which the only choice is between the more formidable operation and closure of the incision without completing the operation

The *fourth* and last class includes those cases, as we have seen, in which the patient's life is in imminent peril, and something must be done at once both to locate the lesion and to apply means for its relief And strange to say, this is the class in which the so-called conservatism is most frequently shown Illustrative cases of this class are those of gun shot wounds of the intestines, rupture of an extra uterine pregnancy, perforation of intestine during typhoid fever, rupture of an abscess into the peritoneal cavity, or rupture of the urinary or gall bladder, or of rupture of the pregnant uterus, with escape of the fœtus into the abdominal cavity, as reported by Plenio, in a recent number of the *Centralblatt fur Gynakologie*, in which the patient's life was saved The successes of Bull and Hamilton with gunshot wounds of the intestines are alone sufficient to warrant an explorative laparotomy when such cases occur, and in regard to operating for ruptured extra uterine pregnancy we need only refer to the successes of Mr Tait Almost two years ago Mikulicz reported a successful case of laparotomy and suture of the intestine for a ruptured typhoid ulcer He has reported an unsuccessful case of operation for rupture of the stomach, but the patient was collapsed before the operation was begun, and an unsuccessful case of operation for perforation of the vermiform appendix, but it was not undertaken until twenty-three hours after the accident Lloyd reported a case, unsuccessful, for gunshot wound almost three years ago, but the operation was not performed until the fourth day So far as we are aware the successful cases have been those in which the operation was performed early Nevertheless it seems that, when the surgeon sees the patient at a late date for the first time, he should still perform the operation

---

In connection with the latter part of the preceding paragraph it may be asked whether commencing or existing peritonitis contraindicates an operation Fortunately, the successes and experiences of Schramm, Boully, Israel, Litten, Keith, Wells, and others have already given a negative answer to this question Peritonitis occurs but rarely after operations compared with its frequency after accidents, and it has several times been shown that it rapidly subsides, when due to traumatism, after an operation has been performed, the abdomen washed out and drainage established As regards the operation itself, Mikulicz says, in *Sammlung klinischer Vortrage*, No 262, that it is a secondary question to that of diagnosis, that is to say, he does not now hesitate to perform laparotomy in cases in which the symptoms point to an early death as he did a few years ago Consequently, as these cases may imperatively demand an operation, the easiest and surest way to get out of the difficulty is to make an explorative laparotomy This establishes the diagnosis, and if an operation be demanded the first steps have already been taken The risk to the patient is very much less when the operation is performed before a local peritonitis has become general

---

The importance of laparotomy for diagnosis is well illustrated by a case reported by DR W GILL WYLIE, at a recent meeting of the Obstetrical Society of New

York The patient, who had a tumor which had been diagnosticated as an extra-uterine pregnancy, had an attack of syncope, followed by profuse diarrhœa, and the tumor subsided Dr Wylie made an incision and found a huge pyo salpinx, which was removed The patient recovered Some time before this electricity had been applied for ten days for the supposed extra-uterine pregnancy

THE TREATMENT OF CHRONIC HEART DISEASE BY MEANS OF BATHS AND GYMNASTIC EXERCISES

As stated in our preceding editorial article upon this subject, (THE JOURNAL, January 16,) DR SCHOTT advises the baths for patients with disease of the heart in the stage of ruptured compensation to be diluted and but gradually brought up to the strength of the natural waters of Bad Nauheim The strongest of these, he says, contain from two to three per cent of the chloride of sodium, and from a half to one per cent of the chlorate of lime, and three grammes of CO_2 to the litre of water Only as the vigor of the heart increases, is the individual given a bath containing carbonic acid gas

As in the case of the salts, the proportion of the gas is increased by degrees, until the bather is able to endure the saturated and powerfully charged water of the natural spring In order to artificially impregnate the bath with carbonic acid gas, Schott uses equal parts of bicarbonate of soda and a 42 per cent solution of hydrochloric acid He begins with a kilo of each to 250 litres of water The soda is at first dissolved, after which the acid is added by allowing it to flow by its own weight out of the mouth of a bottle, held beneath the surface close to the bottom of the tub, and cautiously moved about The impregnated water must then be kept as motionless as possible, in order that it may not part with its gas However great the care observed in charging the bath, a layer of gas will form above the water, this must be gently waved aside If now a person be immersed in such a bath, his body becomes covered with a layer of gas bubbles and the skin assumes an erythematous blush The cutaneous irritation thus produced is very beneficial Such a bath stimulates the muscular and nervous systems, and excites circulation and respiration of a healthy person, while upon a diseased organism, Schott believes the effect to be still more pronounced

Beneficial as in an artificial bath, the natural water, which at the spring gushes over the body of the patient, exerts a far greater and more beneficial stimulation The venous hyperæmia, consequent upon the cardiac disease, is relieved, the arterial system is better filled and the weak heart by reason of lessened internal pressure is enabled to contract upon its contents more efficiently The dilatation of its cavities due to impeded circulation is diminished, while, in consequence of the ampler flushing of the coronnary arteries with blood, the heart-muscle becomes better nourished Schott appears to attribute all this improvement to stronger ventricular contractions, as the primary result of the bath It seems to us, on the contrary, that the increased vigor of the systole is secondary to the derivative action of the bath, by which the blood is called from the capillaries and veins into the arterioles

Now come Schott's system of giving gymnastic exercise and its effect This is very simple but methodical, and consists of movements designed to call into play the chief muscles of the entire body Space forbids a detailed description of these It suffices to say, the arms, trunk and legs are successively extended, flexed and rotated against slight resistance This resistance is preferably obtained through another person, who exerts gentle pressure with the hand upon the extremity in a direction opposite to that in which it is to be moved The exercise must never be carried to the point of noticeably accelerating the respiration The patient is directed to engage in conversation while exercising, and so soon as his utterance becomes embarrassed by breathlessness, or the attendant observes that his nostrils begin to manifest labored respiration, the movement is stopped until tranquil breathing is regained Schott claims that, if systematically and judiciously carried out in regular cycles of movements from the upper to the lower extremities, this gymnastic exercise proves not only not monotonous, but also extremely beneficial Not only do the muscles generally become developed, but that great involuntary muscle, the heart gains in strength Moreover, the same effect upon sluggish venous circulation is exerted as by the employment of balneotherapeutics Either treatment alone, is considered by Schott as curative, but when combined their effect is said to be astonishing

Schott does not claim that the valvular lesions themselves can be removed, any more than the structurally altered cardiac muscle can be restored to its original form elements He declares only that by this method of therapeutics hypertrophy may once more be made to gain the upper hand over dilatation This certainly looks reasonable, and the management of this class of cases by other than chiefly medicinal agents is rapidly taking rank among the most approved and advanced therapeutics As Schott says, the time is fast approaching when the practitioner who does not recognize and employ baths and exercise in the treatment of chronic heart disease, will be considered as either ignorant or culpably remiss. It may be considered troublesome, but the practice of medicine is full of measures, the employment of which is tedious and troublesome both to physician and patient.

We cordially recommend to the doctors in charge of appropriate hot springs that they investigate and adopt the suggestions of Dr. Schott in connection with their resorts. Why should we Americans allow our Teutonic confrères to monopolize this line of treatment, or, even employ it with greater system and thoroughness than we? Let us show them that we too are wide-awake.

THE PHYSIOLOGY OF DISSEMINATED SCLEROSIS

DR. JEAN GASTERNATZVY reported about four years ago the results of some experiments on dogs and cats, which show that the trembling observed in disseminated *sclerose en plaques* appears, as regards its origin, to be a consequence of a lesion of a certain extent of the antero lateral roots of the spinal cord, which transmit the impressions which determine voluntary movements. He now reports, in *Le Progres Medicale*, of December 26, the results of experiments made to determine the source of the tremblings in cases in which there is no lesion of the cord, setting out with the supposition that they are the result of some alteration of certain portions of the brain, of the grey matter of the cerebral hemispheres, for example.

In some of his experiments in which he pricked the antero lateral roots of the lumbar plexus, in order to obtain intentional trembling, excitation of the psychomotor centres with a faradic current, after anæsthetization of the animal, caused marked trembling not only in the posterior extremity, the nerves of which issued from the cord at the level of the parts irritated, but also in the anterior extremity, the medullary centre of which was in a normal state. Having noticed this phenomenon, he thought that the trembling in the anterior extremity under these circumstances was perhaps the result of chloroformization, or due to the enfeeblement of the physiological functions of the psychomotor zone, caused by the chloroform. This hypothesis was confirmed by the fact that he was obliged to apply a faradic current of much greater intensity than that usually necessary to cause certain movements of the limbs in a non-chloroformed animal.

The hypothesis was proved to be correct by the following experiments. The psychomotor zone of one side is laid bare, the dog not being narcotized, the psychomotor centre of one extremity is then irritated by a faradic current from a Dubois-Reymond apparatus. The animal is then chloroformed, and the same point in the psychomotor region is again irritated. This must be done very carefully in order to avoid injuring the centre, the electrodes being applied only two or three times and very lightly. In the first experiment irritation of the psychomotor centre of the anterior extremity caused feeble flexion of the left leg with the bobbins at a distance of 200 mm., at 150 mm. the flexion was very strong. The animal was then chloroformed, and five minutes afterwards there was no movement with a separation of 200 mm., and only very feeble flexion with 150 mm. separation. After twenty-five minutes irritation of the centre of the same extremity gave rise, with 150 mm. separation, to feeble flexion with tolerably well marked trembling. Thirty five minutes after anæsthetization, irritation of the same centre caused, at 150 mm., very feeble flexion with very marked trembling in the left leg. Other experiments were made in the same manner, which showed that under the influence of chloroform the excitability of the cortex of the cerebral hemispheres gradually diminishes, the movements become enfeebled at the same time, and the trembling then appears.

In another experiment the psychomotor zone was laid bare on the right side, the animal not narcotized. The centre of the anterior extremity was touched, with the bobbins 250 mm. apart, which immediately caused an epileptic attack with dilatation of the pupils, and spasms which were at first tonic, but then became clonic. After complete chloroformization, with a separation of 50 mm., irritation of the same centre caused irregular and interrupted contractions in the left extremity, without an epileptic attack. This experiment well illustrates the degree to which chloroformization enfeebles the excitability of the grey matter of the hemispheres, since the bobbins had to be brought 200 mm. nearer together than before the animal was chloroformed. In these experiments with faradic currents only the grey matter was irritated, and it is seen that the intensity of the current had to be increased in order to obtain certain movements when the animal was anæsthetized. It must therefore be concluded that the excitability of the psychomotor zone was diminished by the influence of the anæsthetic. On the other hand very pronounced trembling appeared only after the animal was chloroformed, which seems to show positively that it was due to the enfeeblement of the functions of the psychomotor centres.

The practical deductions from these experiments are of great importance in showing that these tremblings have their seat of origin in the grey matter of the cerebral hemispheres As an example, Gasternatzvy cites the paralytic trembling seen in persons affected with progressive paralysis of the insane The essential lesion in this disease consists in part of peri encephalitis, and it is well-known that this pathological process causes atrophy of the cortex, with disappearance of the nerve elements and proliferation of the connective tissue, pigmentation, etc , as shown by Meynert, Huguenin, Magnan, and others, and it is probable that these products cause irritation of the nerve cells of the cortex before they have entirely lost their functions "On the other hand, the paralytic trembling, one of the more important symptoms of this disease, furnishes us certain signs which show its dependence upon the grey matter of the cortex 1 This trembling is general, and its existence in all the voluntary muscles of the body shows that the lesion which causes it is found in a part of the nervous system with which all these muscles are in communication, and the grey matter of the cerebral hemispheres in this region 2 This paralytic trembling always accompanies other symptoms which, as is known, undoubtedly depend on certain lesions of the grey matter of the brain, for example, the symptoms of progressive dementia, analgesia, epileptiform attacks, vaso motor phenomena etc 3 At the commencement of the disease the trembling is scarcely sensible during slightly extensive delicate movements, which are ordinarily the most complex and most coordinated, as the disease gradually advances trembling occurs Finally, in the last period of the disease the trembling causes complete paralysis of all psychomotor or voluntary movements Consequently a relation exists between the paralytic trembling and the other symptoms of the disease on the one hand, and on the other with the progressive development of the pathological process of the cerebral cortex, which constitutes the essential lesion of the disease "

Dr Dmitry Egorovitch Min, one of the most distinguished members of the Russian profession, recently died in his 68th year He was the founder of the Museum of Forensic Medicine in Moscow, was Professor of this branch in the University of that city, and educated the first experts for the reform courts A good poet and an excellent linguist, he probably did as much for general literature as for his profession, having translated in verse *King John*, *Don Juan* and *Siege of Corinth*, Schiller's *Song of the Bell*, Tasso's *Liberated Jerusalem*, and the *Divine Comedy*

SOCIETY PROCEEDINGS

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

Regular Meeting, December 9, 1885

The Chairman, F J Knight, M D , in the Chair

Albert N Blodgett, M D , Secretary

Dr G M Garland, of Boston, read a paper on

SOME CASES OF REFLEX NEUROSIS

(See page 62, Journal of January 16)

Dr Rotch said that the cases described by the reader were of unusual clinical importance from the fact that they occurred in adults, in whom symptoms of reflex origin are rare in comparison with infants and children, where this class of cases reaches its highest development, owing to the hypersensitive condition of the child's nervous system These reflex phenomena are so pronounced in early life that we recognize in them the most serious obstacle to our making an accurate diagnosis, knowing well that any one of them may at times represent many and entirely opposite forms of disease, although the lack of speech of the infant, and the incorrect answer of the older child appear, at first, to offer the greatest barrier to a proper appreciation of the case As general examples of reflex symptoms, we have the different forms of eclampsia, the vomiting of cerebral disease, and the earache arising from irritation in the mouth during the dental periods He mentioned some special cases occurring in his own practice which seemed to illustrate the class of cases referred to in Dr Garland's paper

Case 1 —A child two years old was seized with dyspnœa and cough, which continued until a purulent discharge from the ear drew attention to that organ, and inflammation of the Eustachian tube was followed by immediate relief to the symptoms There had been no other signs of aural disease, and a physical examination had disclosed nothing abnormal in the heart or lungs

Case 2 —A child four years old had a chronic otorrhœa , whenever treatment directed to the ear stopped the discharge, the child began to have what appeared to be a laryngeal cough, though nothing abnormal could be found anywhere on examination of the air-passages, the cough would continue until the discharge from the ear returned, and then would cease, and this reversal of symptoms would occur four or five times in a year

Two cases seen in consultation with Dr Minot presented the following peculiarities, illustrating the difficulty of making a diagnosis from the rational signs, on account of misleading reflex symptoms Case 1 had pneumonia of the left dorsal base Case 2 had acute inflammation of the middle ear When seen by Dr Minot, the child with pneumonia had normal respiration, no dyspnœa, pale skin, and was sleeping quietly, while the child with ear trouble had respirations of sixty to seventy, dyspnœa, flushed face, and was relieved by inflation of the Eustachian tubes

Rosenstein's case of supposed purely reflex neurosis of the intestine is worth mentioning A boy nine years old began to vomit fæcal matter, and, at at the same time, to have fæcal discharges from the rectum This continued for five weeks, with short intervals, and finally disappeared and did not return Enemata in this case caused both rectal discharges and stercoraceous vomiting, and the treatment which finally gave relief was the administration of bromide of potash and chloral

Another class of cases supposed to arise from gastric irritation is the so called asthma dyspepticum—in which infants and children are seized with rapid respiration, dyspnœa and cyanosis, the temperature remaining normal, and nothing but harsh respiration being found on examination of the thoracic organs These symptoms are promptly relieved by an emetic, and are probably due to irritation of the vagus

Under the head of a reflex neurosis we may also possibly classify peculiar nervous phenomena which I have met with at my children's clinic at the Boston Dispensary, where the sole symptom in one case, a boy of five years, was hiccough, lasting for many weeks, and in another, a boy of nine years, gasping respiration occurring every three or four minutes We must, however, allow that these last two cases might have been symptomatic of hysteria, or of simulated disease for the purest type of the disease hysteria is represented in young children, especially in the first four or five years of life, where the simulated symptoms of the malingerer, marked examples of which I have met with would be extremely unlikely to arise as a complication

Finally, there is a class of cases in which I am especially interested, and which, after carefully investigating, and having ample opportunity for following closely and making a precise eliminative differential diagnosis, from digestive disturbances and organic disease of the stomach, I am forced to consider a reflex neurosis, connected possibly with the great abdominal ganglia of the sympathetic, perhaps some shock to these ganglia causing a temporary paralysis of the controlling sympathetic nerve filaments of the stomach, resulting in uncontrollable gastric peristalsis The patient, whether infant or child, is in perfect health up to the onset of the attack, it then suddenly begins to vomit, and this, in some cases, is repeated regularly every fifteen minutes by the clock, for many hours, or it will vomit, then seem pretty well for twelve or even twenty four hours, and then have continuous vomiting for eight or ten hours, then the intervals of vomiting grow longer, and the attack stops suddenly in about thirty-six hours, after which the patient rapidly regains its strength, this may occur many times during the year, then may omit for a whole year, but pretty surely returns, and usually lasts until puberty Absolutely no other symptoms could be discovered in these cases, excepting great thirst and prostration, following the loss of fluid from the body, and the mechanical fatigue The temperature was usually found to be normal, and the bowels not especially constipated, the cases were evidently not induced by the ingestion of improper food, in young infants, the prostration was at times so great as to produce serious doubts as to their recovery All treatment directed to controlling the vomiting has so far failed, the disease apparently being self limited, but the main factor in supporting the patient's strength during the attack is to from time to time, according to the pulse and general aspect, produce sleep, which is accomplished by enemata of bromide of potash and chloral, which at times also seem to render the intervals of vomiting longer, though they do not materially shorten the length of attack The late Dr Calvin Ellis saw a number of these cases, and considered them of reflex origin Dr Minot also was of the same opinion when he saw a case of this kind with me I have never heard of a death from this disease, but I think that in young infants it might occur from exhaustion unless sleep could be produced I am inclined to attribute the cause clinically to exhaustion of the sympathetic from some shock, perhaps mental, in peculiarly sensitive subjects, and I have arrived at this conclusion by a process of careful elimination, no definite point of irritation so far having been discovered in other parts of the economy nor any proof that there has been irritation of the gastric terminal filaments of the vagus

The cases occurred at all ages and among all classes, and I would say once more that the theory which I have advanced as the cause of this disease is the result of six years' clinical study of special cases, and that I present it to this Section for Clinical Medicine with much modesty, for so far as I know, no one else has as yet concurred with me in my idea as to the sympathetic ganglia being the nidus of the disease, although all agree, so far as I know, that it is of reflex origin

DR HENRY I BOWDITCH said that he was much interested in the subject of the paper, which is a matter of great importance to the physician The cases mentioned by Dr Rotch do not fall into the same category as those contained in the paper Dr Bowditch never thought of these cases as caused by a reflex neurosis, but as caused by some disturbance of digestion It is to be regretted that the reader has not given us a *resume* of the present state of science on this subject

Dr Bowditch spoke of a woman whom he had recently seen, in consultation, who had some menstrual trouble, accompanied by constant cough No positive causes could be found for the symptoms, but a sensitive spot was discovered in the lower right abdominal region The diagnosis of threatened abscess of the broad ligament was made, with tumefaction of the ovary This was the cause of a severe cough which was in this case evidently of reflex origin

DR BLODGETT mentioned a case in which a man of middle age was the subject of a periodical attack of what he called "biliousness," which always commenced by a feeling of dull distress in the region of the liver, and was soon followed by a swelling of the lower jaw, but upon the other side, that is to say, on the left The swelling is very painful, so that the patient is obliged to give up all business and keep the house, and at times to remain in bed   The curious part of the case is that a prompt cathartic will cause the swelling of the jaw to disappear in a few hours, with complete relief to all the symptoms   The jaw gives no further trouble until another attack of "biliousness" occurs, when the former symptoms reappear in all their intensity

Dr Garland in closing the discussion, stated that our present knowledge of reflex phenomena is not at all satisfactory   In Germany much interest is at present manifested in the subject of reflex neurosis, and cases are reported corresponding closely to those described by Dr Rotch   Dr Rotch's case of vomiting well illustrates in children the same phenomena which Professor Leyden has noticed in adults, and Professor Leyden reports a case of this kind where the post mortem examination showed no organic disease, and where the symptoms during life consisted merely of continuous vomiting   This subject also occupied largely the attention of the German Congress of 1884, and the discussion was opened at that time by Professor Leube   Dr Garland also said that a year ago, he had met with a case which illustrated this condition of gastric neurosis, the symptoms being vomiting and the autopsy negative

Dr H C Haven read a paper on

THE ETIOLOGY OF RACHITIS

(See page 91)

Dr Rotch in opening the discussion, stated that he did not remember the exact number of the cases of rachitis which he had seen at his clinics at the City Hospital, Boston Dispensary, and Children's Hospital during the last two years, but that he had collated them, and that he was under the impression that the number of cases where it occurred in colored children, was small in comparison to the white   This might, however, be accounted for by the fact that his clinics were not situated in a colored district, while the Dispensary of the Infant Hospital was in a portion of the city thickly populated by the colored race   This might bring a larger number of colored rachitics under Dr Haven's care, but still would not account for the large per cent of rachitics among the whole number of colored patients   He agreed with Dr Haven as to the probable influence of climate as a cause, but he also offered the following suggestions as perhaps aiding the future study of the subject   It has been noticed by some of our Dispensary physicians that venereal disease is especially common among the colored portion of the population   If this be so, and syphilis is more common among the colored people, hereditary syphilis would also be more common, and although we recognize that there is no direct connection between syphilis and rachitis, yet, for some years, the most prominent physicians in children's disease in Germany have held that even where hereditary syphilis has been cured, these same children are more apt to have rachitis than those who have not had syphilis, simply from their syphilis having left them in a condition favorable to the development of a disease, such as rachitis, represented by impaired nutrition

Dr Rotch also said that the number of rachitics which were presented at his clinics had increased during the last six or seven years, and that he remembered being struck by the small number of cases of rachitis, which he encountered among large numbers of poor children who came under his observation on his return from Vienna some years ago, where the number at that time was much larger proportionately than in Boston, and yet where the physicians insisted on calling the disease the "Englische Krankheit "

He also drew attention to the results of autopsies observed by himself and others, pointing towards a possible rachitic condition of the bones of white children, without any manifestation of this condition during life, the cases being merely diagnosticated and treated as debility from impaired nutrition   Thus a well-marked rosary is at times found on the inner surface of the costal cartilages, where no suspicion of such a condition was detected during life, and it may be that there is a greater predisposition among the colored race to show the external manifestations of rachitis among the whites

Dr Bowditch said that Dr Haven had made an important addition to our knowledge upon the racial and climatic relations of rachitis, and expressed the hope that he would carry on on his observations to a still further extent, and by means of the United States consuls and other officers of the government, obtain information as to the condition of the colored populations in Africa

Dr Haven replied that he had endeavored to obtain the desired information from the National Library at Washington, but had not been successful

Dr F B Harrington, of Boston, then read a paper on

THE PULMONARY COMPLICATIONS OF TYPHOID FEVER.

(See page 86)

Dr Vickery remarked that in the stupor which is often associated with typhoid fever, it is easily possible that portions of food may be aspirated into the lungs, thereby inducing a pneumonia from the presence of the foreign body in the air passages

Dr Bowditch stated that in typhoid fever there is often a lack of the more striking symptoms belonging to other serious diseases, so that they may often be easily overlooked   All febrile diseases present the same general features as certain cases of typhoid, and many cases are, no doubt, ranked as typhoid which are in reality something else   It is certain that many pulmonary affections are ranked as typhoid which have nothing to do with that disease

Dr Haven showed an

IMPROVED FORM OF STETHOSCOPE,

consisting of an ordinary Camman instrument, in which the usual flexible tubes are replaced by similar tubes about two feet in length, which allows the physician to stand at a somewhat greater distance from the patient, and in some cases as, for instance, in the presence of pediculi, is a source of great comfort   In the examinations of children it is of much convenience, as it allows greater adaptation to the movements of a fretful patient   It is quite portable, and gives almost the same concentration of sound as does the ordinary instrument

Dr Haven also showed an

IMPROVED FORM OF NURSING BOTTLE,

by which the natural conditions are more perfectly imitated than in the forms of bottle generally in use It consists of a flattened and elongated glass bottle, one side of which is removed so that the atmosphere may exert its normal pressure on the contained fluid, and thus imitate the normal conditions of infant feeding Another desirable feature is that every part of the bottle is accessible to cleaning, and a rubber nipple is used in which several fine holes are made by a cambric needle The effort of suction by the child is sufficient to excite the salivary glands of the child's mouth, and thus promote the normal digestion of the food

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, December 16, 1885

THE PRESIDENT, W W JOHNSTON, M D,
IN THE CHAIR

T E MCARDLE, M D, SECRETARY

Dr J F Hartigan presented a specimen of

RUPTURE OF THE ILEUM,

all the coats of the gut having been ruptured by a kick on the abdomen The patient and his assailant were adult males No external marks of violence could be found The intestinal contents were emptied into the abdominal cavity and the man died of collapse and peritonitis two days after the injury The wound was necessarily fatal, but he had presented the specimen as having some bearing on the subject of laparotomy He has made autopsies on five persons who died from kicks on the abdomen In three of them there were no external evidences of violence One died from the kick of a horse, two were kicked by mules, one by a woman, and the fifth by a man

Dr Richey reported a case of

CHRONIC SIMPLE GLAUCOMA TREATED WITH ESERINE

Patient was a female, aged 37, with absolute glaucoma of the left eye The vision of the right was $\frac{20}{200}$, much blurred She had seen the halo at 18 years of age, and thought she did so with the left eye, which did not become blind until seven years ago T 3, pupils half dilated, shallow anterior chambers, anæsthetic cornea in both, though she thought the left had been affected only since the other became blind No pain or inflammatory symptoms at any time The treatment was liq potassi arsenitis, gtts ij, t i d, iodide of potassium, grs v, after each meal Eserin sulph (gr 1/8 f ℥) instilled, twice a day, and dry cups to the right temple

Under this treatment from January 21 to March 28, 1885, *tension* became normal, $V = \frac{20}{20}$ Anterior chambers natural and pupils normal in size Eleven months later the condition was the same He prefers eserine to pilocarpine because it is not so spasmodic in its action, and the eserine in mild solutions, thinking they are less likely to cause follicular conjunctivitis, as reported by De Wecker

Dr Swan M Burnett said that we knew just enough about glaucoma for the imagination to run riot As to actual facts, however, we are sadly deficient in knowledge There is no disease that the ophthalmic surgeon fears as much as glaucoma Dr Richey thinks he has cured this case with eserine, but Dr Burnett doubted if in six other cases one would be benefitted He thought the doctor had not given sufficient credit to his great care of the patient's general health He had seen so many things tried in vain for the treatment of this disease that he had begun to believe that we can not rely upon anything The disease is slow in its progress and may go on from year to year without increase of tension One of the leading ophthalmologists of Paris says that an iridectomy for this disease is pernicious in its effects, the patients get worse This fact was verified by some cases under Dr Burnett's observation Judging from statistics collected by his assistant at the Dispensary, a larger number of females than males are affected by this disease This is especially true of nervous women about the climacteric period Dr Burnett had examined Dr Richey's patient, and had found the condition just as the doctor stated it It is quite remarkable that such an amount of pressure should continue for such a long time and produce no more effect on vision It is difficult to form a correct idea of the amount of pressure in a glaucomatous eye He related an illustrative case His patient was a man suffering from glaucoma The vision was lost An iridectomy was successfully performed In six months there was a second attack in the same eye, with subacute symptoms Constitutional remedies were given and the disease held somewhat in abeyance It was finally decided that the only thing which could give relief was enucleation The patient at first refused to submit to such an operation But the cicatrix began to open and gradually the crystalline lens was pushed forward and came out of the opening the morning of the day Dr Burnett enucleated the eye He wished to call attention also to the insidiousness of this disease, and to the liability of its being mistaken for some other trouble It is important to make a correct diagnosis early, for the difference of a few hours may mean loss of vision He related a case in point in which the patient, a colored woman, had been under the care of a physician for six weeks without a proper diagnosis having been made Dr Burnett was compelled to perform sclerotomy The pain was relieved but vision was not restored In this case he vainly tried to cocainize the eye, and was forced to resort to general anæsthesia He had observed the same thing in other glaucomatous eyes Tension would seem to prevent the cocaine having its usual effect

Dr Richey said that Dr Burnett had rather left the strict consideration of the paper He had not intended to give a comprehensive treatise on the disease in his paper, but rather to bring out a few salient points as evidenced in his case and treatment

The case will probably ultimately result in blindness Hardly any other result is to be expected The subject of increased tension has occupied specialists for a long time, and it is now considered pathognomonic of glaucoma The chronic form is the most insidious

Dr Burnett did not remember having ever before seen this disease in a patient eighteen years of age He would give a more hopeful prognosis in the present case than that given by Dr Richey

Dr Richey said he had endeavored to correct the fermentative dyspepsia from which the patient suffered Apart from that she was in fairly good health He had also given her iodide of potassium, and had used dry cups Judging from what he had seen of chronic simple glaucoma, he would not be inclined to give a favorable prognosis Whether the good result already obtained was due to eserine or not, he did not know He thought, however, that eserine, and not atropia, was the proper remedy, though some have reported good results from the use of the latter drug He had no confidence in pilocarpine In reply to a question by Dr W W Johnston as to the pathological histology of the disease, Dr Richey said we glean much of our knowledge from post mortem examinations Acute glaucoma is caused by something which interferes with the escape of fluid, though the secretion continues There being no escape, the retina is obtunded and the circulation interfered with Sometimes inflammatory changes occur, but not in chronic simple glaucoma

---

Stated Meeting, January 4, 1886

The President, W W Johnston, M D,
in the Chair

The following officers were elected for the ensuing year

President—Dr C H A Kleinschmidt

Vice-Presidents—Drs W H Taylor and J B Hamilton

Corresponding Secretary—Dr T C Smith

Recording Secretary—Dr T E McArdle

Librarian—Dr J H Mundell

Treasurer—Dr C W Franzoni

Board of Examiners—Drs McArdle, Fry, Acker, L Tyler, and E C Morgan

Board of Censors—Drs Cook, Holden, and Hyatt

Publication Committee—Drs McArdle, Harrison, Fry, and Adams

Committee on Microscopy—Drs Lamb, Aiken, and Harrison

PATHOLOGICAL SOCIETY OF PHILADELPHIA

Stated Meeting, January 14, 1886

The President, J C Wilson, M D, in the Chair

W E Hughes, M D, Recorder

Dr T S K Morton presented a

CANCER OF THE LOWER THIRD OF THE ŒSOPHAGUS, WITH METASTASES TO THE STOMACH AND LIVER,

from a woman æt 61 years, of good family history Her illness commenced, by her account, eleven weeks before her death, with jaundice, vomiting, constipation, and lancinating pains in the right hypochondrium The vomiting became uncontrollable, the matters several times containing coffee-ground material After death there was found a scirrhus cancer of the lower third of the œsophagus extending to the stomach, with no narrowing of the œsophageal lumen The retro-peritoneal glands were involved, and the head of the pancreas slightly Scattered through the liver and stomach were numerous secondary nodules

Dr Morton then presented a specimen of

CIRRHOSIS OF THE LIVER WITH PERI-HEPATITIS,

removed from the body of a woman, æt 40 years, who had been an excessive consumer of strong spirits Symptoms had been present for five years, the most prominent of which were general œdema with marked ascites and diminution of the area of liver dulness She died of an intercurrent attack of facial erysipelas The liver weighed thirty six ounces and was strongly adherent to neighboring structures At its entrance into the liver the portal vein was much contracted, and below this point dilated

Dr Morton also presented a specimen of

AMYLOID DEGENERATION FOLLOWING CHRONIC DYSENTERY

The patient, a girl, æt 20 years, had no history of syphilis, there was a perfectly good family history She had been in poor health, but with no positive symptoms, for two years Last summer she had whooping cough After that she improved steadily till three weeks before her death, when profuse diarrhœa with high fever set in This was the first attack of looseness of the bowels she had had Jaundice gradually developed The liver was found to be enlarged The urine contained albumen and casts The diarrhœa persisted, the passages containing blood and pus At the autopsy the liver, spleen, and kidneys were found infiltrated with amyloid material, and the large intestine was throughout in a state of chronic dysenteric ulceration

Dr James Tyson said this was the first case he had ever met with in which there was this association of amyloid disease with dysentery as the etiological factor, although this seems the only possible cause in this case, in which the possibility of syphilitic disease seems excluded

Dr William Osler thought it was well recognized that chronic dysentery might be followed by extensive amyloid disease He had met with one or two instances in connection with chronic diarrhœa, which post mortem examination showed dependent on chronic dysentery, with very much the condition of bowel present in Dr Morton's specimen

Dr William Osler presented a

SPINDLE-CELLED SARCOMA OF THE RETRO PERITONEUM WITH EXTENSIVE THROMBOTIC DEGENERATION,

and gave a history of the case A man, æt 60 years, was admitted to the University Hospital in September, 1884, with an abdominal tumor which had been noticed for about six months He had lost flesh and strength, but there was no pain The tumor formed a solid mass, occupying a median position extending above the umbilicus, and could be readily separated by palpation from spleen and liver The case was regarded as one of Lobstein's retro-peritoneal sarcoma For several weeks the patient passed daily over seven pints of clear urine, of low specific gravity, without sugar or albumin The patient was subsequently admitted to St Mary's Hospital under Dr O'Hara, and while there Dr Mears aspirated the tumor, the upper part of which had become soft, and drew off nearly two quarts of bloody serum At the autopsy the tumor was found to occupy a central position, was covered by peritoneum, and was attached to the tissues in front of the symphysis pubis, and seemed to have grown from the subperitoneal connective tissue in this region The upper part of the mass was represented by a soft fluctuating cyst containing blood and shreds of firm thrombi, the greater part formed a solid mass, which on section presented a brownish red color, was firm and dry, and had all the appearance of an old unstratified thrombus In an area of at least 8 × 7 inches this remarkable condition existed At the lower part there were two or three grayish white masses, evidently of a sarcomatous nature The capsule was formed of condensed fibrous tissue, beneath which in many places were recent extravasations The weight was estimated as at least eight pounds The lymphatic glands were not enlarged The kidneys were fibroid The liver presented several secondary masses, one the size of an orange Microscopic examination showed the primary and secondary masses to consist of closely packed spindle cells The reporter drew attention to the rarity with which spindle celled sarcoma forms a large abdominal tumor, and to the unusual site of origin The most interesting feature was the remarkable transformation which the greater part of the mass had undergone This was attributed to repeated hæmorrhages and the gradual conversion of the extravasated blood into a dry, hard thrombus Such a thrombotic change in a tumor was most unusual, and he had not been able to find reference to a similar instance A third point referred to was the polyuria, which was doubtless due to irritation by pressure on the renal nerves Reference was made to the facility with which the growth might have been removed

DR J EWING MEARS thought the growth could have been removed, though the removal would have been attended with some hæmorrhage

DR TYSON asked Dr Osler what, in his opinion, was the effect of thrombotic degeneration on the histological elements of tumors, and whether it was possible for clots to be converted into the tissue of the original tumor, as is asserted by some?

THE PRESIDENT remarked that the case was of much interest from a clinical standpoint, in view of the possibility of surgical interference, and asked Dr Osler whether the conditions as found *post mortem* suggested any means by which such a tumor as this could be diagnosticated from a similar growth occupying the more usual position in the lumbar region

DR TYSON, in connection with the clinical history, called attention to the retro peritoneal sarcoma presented by him to the Society last winter, which had been mistaken by him and others for a tumor of the kidney

DR OSLER, in reply to Dr Tyson's first question, stated that the only remnants of sarcomatous tissue were two or three small but very distinct portions in the lower attached part of the tumor, the remainder had wholly undergone this thrombotic change, and in the upper part had become converted into a blood cyst This change was no doubt slow, with first a destruction of the sarcomatous elements by the blood clot, and then a slow process of necrosis There was no evidence in any part of the tumor of an invasion of the coagulum by the sarcomatous elements, as is not infrequent in thrombi in other regions, as he had seen in the portal and renal veins The chief interest in the specimen lies in the remarkable extent of the thombotic change Looking at the clinical aspect, he had diagnosticated the case as one of retro peritoneal sarcoma from its large size, its being so centrally placed, its slight movability, its distinct separation from liver, kidney, and spleen not being placed more on one side than on the other, and from the fact that palpation in the lumbar region gave no pain or other evidence of kidney lesion It was firmer above the brim of the pelvis than any other tumor he had ever examined One remarkable feature about these tumors is their painless character This man complained of no pain, and in two other similar growths, which he described at length, pain was not a symptom

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

The Value of Iridectomy in the Treatment of Detached Retina — Sparteine — Listerism — Dry Antiseptic Dressings

Dr Fano has recently published a paper on the *Value of the Iridectomy in the Treatment of Detachment of the Retina* Iridectomy, the author states, acts in two ways in the treatment of this lesion as an antiphlogistic, as an expedient purely optical He explains that detachment of the retina is not an idiopathic affection, the production of a serous effusion between the choroid and the retina is the consequence of some circulatory trouble in the vessels of the choroid The detachment is only the effect of the serous effusion, and this latter is the result as in all cases of œdema and serous effusions, of an obstruction in the venous circulation In removing a portion of the iris as in iridectomy, a great number of the vessels of the iris are divided, and a depletion of this membrane is thus obtained

The vascular system of the iris having a great number of anastomoses with the vascular system of the choroid, a mediate depletion of the vessels of the latter is also produced The chances of reestablishing the circulation of the choroid to its normal condition is thus afforded, the re absorption of the effused liquid behind the retina, and a radical cure of the detachment of the retina being the consequence In some cases the detachment of the retina is limited to only a portion of this membrane The portion undetached continues to receive the impression of luminous rays, the detached portion acting like a screen, prevents the luminous rays reaching that part of the retina which has preserved its sensitiveness To improve the vision the luminous rays which enter the eye must not be allowed to be absorbed by this screen, but should arrive at the portion of the retina which remains *in situ* In enlarging the pupil by iridectomy a greater number of luminous rays reach the fundus of the eye, increasing the intensity of the image In affording the new pupil a position directly the reverse of that occupied by detachment of the retina, the luminous rays which traverse the new pupil are not arrested by the screen represented by the detached portion Hence, if the detachment is in the upper part of the retina, the artificial pupil should be practised below, should it be in the lower part, the pupil will be above Dr Fano cited several cases of his clinic to show that medicinal treatment is of little or no avail in this affection, and although iridectomy does not effect a thorough cure, yet, the vision is considerably improved and it may prevent the malady progressing

Sparteine is the name of another new substance just introduced by Professor Sée into the armamentarium of therapeutics At a recent meeting of the Academy of Sciences the learned Professor described sparteine as an alkaloid obtained from the *Sparticum scoparium*, which was discovered in 1850, by Stenhouse, so that strictly speaking it cannot be termed a new substance, but a new remedy M See experimented with the alkaloid in the form of sulphate, and the following effects were the result The first was an improvement in the action of the heart and pulse In this respect it is equal to digitalis or to convallamarine, but its effects are more decided, prompt, and durable than either The second effect is the regulation of the rhythm of an irregularly acting heart, in this respect no other drug is said to be compared to it The third effect observed is that of increasing the rate of the cardiac contractions, thereby rendering a slow pulse more frequent, thus acting like belladonna

All these phenomena appear within a few hours after the administration of the drug, and last for three or four days after its suppression During this time the general strength is increased, the breathing becomes easier, but the urinary function alone does not appear to be influenced by the alkaloid in moderate doses The indications for its administration are sufficiently clear, that is, the sulphate of sparteine may be usefully employed in all cases of weakness of the myocardium, whether it be the result of an alteration of its tissue, or whether it has become insufficient to overcome the obstacles to the circulation When the pulse is irregular, intermittent, arythmical, the sulphate of sparteine rapidly restores it to its normal type When the circulation is slackened, the alkaloid appears to immediately overcome this functional trouble, maintaining or increasing, at the same time, the strength acquired by the muscle Although the sulphate of sparteine may be considered a new remedy, yet the plant from which the alkaloid has been extracted had for a long time been employed in medicine The young sprouts, the flowers and seeds are diuretic and purgative The plant was considered very efficacious in the treatment of dropsies, gravel, albuminuria, and affections of the heart

Listerism, or the so called antiseptic method of dressing wounds, is now scarcely ever employed in surgery, but there is no doubt that in other forms than the spray the antiseptic method has such advantages that a surgeon would be considered culpable of neglect if he excluded it from his practice Its employment in the hospitals in the times of peace is attended with little or no difficulty, but on the field of battle it is a very different matter To overcome the difficulty Dr Bedoin, principal medical officer at Vincennes, proposes that all wet or moist dressings should be rejected, as well as pulverulent dressings, as being impossible to be properly applied, and recommends the employment of tissues previously impregnated with some antiseptic substance, such for instance as ungummed filtering paper, gauze, lint, or jute, as being the most inexpensive These tissues are steeped in a solution of carbolic acid, boric acid, or of corrosive sublimate, then dried The dressing consists in the direct application of these leaves on the wound, the whole being covered with layers of gutta percha and fastened with a bandage The tissues thus prepared are inexpensive, very light, and not bulky By this means the asepticity of the wound is ensured, and it permits of the employment of the more classical antiseptic dressing when once the soldier has reached his permanent ambulance Some of these leaves may be arranged under his cuffs, and the sick-bearers may be supplied with a few packets of them which they may apply themselves A L

DOMESTIC CORRESPONDENCE

THE ETIOLOGY OF ACUTE CORYZA

Dear Sir —The fact that rhinitis, pharyngitis, laryngitis and bronchitis or so called catarrh are caused by micro organisms and not by cold, was forcibly impressed on my mind about two weeks ago For the last month there has been a great deal of wet weather in Pittsburgh, and this, together with the fact that many of the streets of the city have been dug up for the purpose of laying gas and water pipes, setting free these micro organisms, which, as I believe, have been the cause of a sort of endemic of catarrh which has been prevailing here for the last month These micro organisms seem to have found their favorite lodgment in the mucous membrane of the nose, pharynx, larynx or lungs, thereby causing the numerous cases of catarrh which have been prevailing in our vicinity recently

The fact that quinine taken internally in 5-grain doses has been the most effectual treatment in these cases of catarrh, has further induced me to the belief that parasitic organisms are the cause of the so called catarrh How quinine operates as a parasiticide, whether locally, or more remotely by the circulation, I am unable to say, but I am pretty confident that it acts effectually It has been my custom to prescribe 5 grains of sulphate of quinine three times a day for two days, and the cold then would be pretty thoroughly broken up

These facts I offer as bearing out the suggestions as to the etiology of acute coryza given by Dr Austin Flint, Sr, in an article in THE JOURNAL, of November 14, 1885 JOHN M BATTEN

73 Sixth Ave, Pittsburgh, Pa, November 16, 1885

BOOK REVIEWS

ANNUAL REPORT OF THE SUPERVISING SURGEON-GENERAL OF THE MARINE HOSPITAL SERVICE OF THE UNITED STATES, for the Fiscal Year 1885 8vo, pp 179 Washington Government Printing Office 1885

There is much interesting material in this small pamphlet The first twenty four pages contain the official report of the Secretary of the Treasury, the most interesting part of which is a description, by the architect, of the new Marine Hospital at Baltimore, which is to consist of eight buildings Six of of these will form the Hospital portion proper, three being houses for executive business, for the Assistant Surgeon, and for the boiler, engine, dining-room, kitchen, etc, and three being ward buildings All of the principal floors are on one level, and are connected by wide and spacious verandas, which extend entirely around the ward buildings The wards proper are 30 feet wide, 109 feet long, and 16 feet high at the sides, and each will accommodate twenty patients Each ward has two diagonal wings, which can be isolated from direct communication, one containing water closet, bath and lavatories, the other a smoking room The buildings are to be heated by steam or hot water from the boiler room The ground-plan of the hospital is nicely shown on a large folding sheet When completed this will be the seventeenth hospital in the Marine Hospital Service

Passing over an extensive statistical statement to the report of surgical operations during the past year, we find that the femoral artery has once been successfully ligated for popliteal aneurism In a case of gun-shot wound of the popliteal vein both ends of the vein were tied In a case of neuralgia and loss of function of the ulner nerve, 1¼ inch was dissected, the operation resulting successfully Five operations on the knee-joint are reported, one for suppuration of the patella bursa, one for synovitis, two for suppuration of the joint, in which the bone was scraped, and one for loose cartilage Three operations on the skull are reported, one for fracture, in which the skull was trephined, with a fatal result, and two successful cases of removal of necrosed bone Four operations of excision of joints were divided between one excision of the elbow for necrosis, with good results, one of the hip for morbus coxæ, fatal, one for ankylosis and caries of the knee, with good result, and two successful resections of the ankle for caries and necrosis Two successful operations for stricture of the rectum, one by incision and one by divulsion, are recorded We can see no good reason why the names of the operators are not given, as well as a few other particulars concerning the more severe operations As it now stands, the tabulated statement is absolutely valueless for reference

Following the list just mentioned are some "selected cases from hospital practice" The first paper under this head is on *Cases of Peculiar Forms of Fever* by Passed Assistant Surgeon John Guitéras, and is a most interesting account of some of the peculiar forms of fever observed in the Southern portion of the United States The second paper is a report of a case of resection of the ulner nerve for neuralgia and loss of function, which has already been mentioned The nerve was brought together by two fine catgut sutures The wound healed by first intention The pain disappeared entirely from the time of the operation, and three weeks afterwards sensation began to return in the little and ring fingers, a month later in the muscles supplied by the nerve, "and six months after the operation the hand had so far recovered that the man was enabled to whittle out a miniature merchant man with the injured (right) hand" The operation was performed in the Marine Hospital Dispensary, Portland, Oregon, by Assistant Surgeon Arthur D Bevan Passed Assistant Surgeon A T Armstrong reports an interesting case of *Syphilitic Disease of the Pons Varolii* In the substance of the pons was a spherical cavity about one centimetre in diameter Cerebral symptoms first appeared two years after he came under treatment for secondary syphilis "He complained of having suddenly been troubled with pains in his head and dizziness when he was in a high place His pupils were equal in size and no incoordinate movements in walking" Two months afterwards he still complained of dizziness, and of cephalalgia (Feb 28) On April 11th he was admitted to the hospital with paralysis of the right arm and leg, which commenced gradually on the day before On April 13th there was complete right hemiplegia, with difficult speech on account of involvement of the tongue On the 17th he had a fit, somewhat cataleptic in character, "the most marked feature being perfectly rigid muscles" This state lasted about half an hour He died comatose on April 21st The cavity in the pons, already mentioned, involved the median line, but was mainly to the left of it, and was 3 centimetres below the anterior surface "There is one etiological factor for consideration Syphilitic degeneration of the anterior coats was not noticed in this case In December, 1883, necrosis of the left alveolar process of the superior maxilla commenced Probably this caused disease of the left superior maxillary nerve This degeneration extended backwards, and in December, 1884, when the first cerebral symptoms were noted, had effected the point of origin of these special fibres of the fifth nerve in the pons varolii. Here a sympathetic and gradual degeneration of the substance of the pons was initiated, involving adjacent nerve tissue, and interrupting the decussated motor fibres to the cord, with consequent paralysis of the right side. More than this, fibres to the ganglia of the medulla oblongata were degenerated, causing those expressions of medullary epileptiform spasm, and eventual death from interference with the respiratory centres." This explanation is offered as a working hypothesis in the etiology of some forms of syphilitic cerebral disease. Dr. Armstrong also records a case of malignant œdema. The remaining pages are taken up with reports of fatal cases, with autopsies. Among these, under the report of a case of phthisis, is a description of a supernumerary kidney. It was found in the hilum of the left kidney, attached to its ureter by a small duct (ureter). On examination no evidence was found to show that it had performed the functions of a kidney. Probably the most interesting of these reports is that of a case of uræmia, complicated by meningitis from reflex irritation due to renal calculus.

A Guide to the Practical Examination of Urine. For the Use of Physicians and Students. By James Tyson, M.D., Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania, etc. Fifth Edition. Revised and Corrected. With Colored Plates and Wood Engravings. 8vo, pp. 249. Philadelphia: P. Blakiston, Son & Co. 1885. Chicago: W. T. Keener.

The fourth edition of this now standard work on the examination of urine was in the press when the first announcements were made of the new and delicate tests for albumin, and those interested in the subject have looked forward with no little interest to the appearance of this edition. These tests are fully considered in the present edition, and, with perhaps one or two exceptions, have been assigned to what seems to be their proper places. These exceptions are in regard to the picric acid and potassio mercuric iodide tests, and the test papers for the detection of albumin. In the case of the potassio mercuric iodide test we cannot agree with the author that the urine requires no previous acidulation. "In my own experiments," says the author, "I have several times failed with the mercuric iodide when I succeeded both with picric acid and sodium tungstate." It is entirely probable that his want of success in such cases was due to the fact that he did not add citric acid, as advised by Oliver and practised by Ralfe.

It seems scarcely necessary to give any detailed description of Dr. Tyson's book, as almost everyone seems to have seen or used one of the earlier editions. For its size it contains more information as to the proper methods of testing urine than any book in existence. It is clearly written, the directions being concise and in such language that the veriest tyro should understand them. The chapter on urinary deposits is much more full than is found in many larger volumes. It contains a colored plate showing pigmented markings on glass slides, which will be regarded with interest by many a man who has been puzzled by such an appearance under the microscope.

To one who has paid little or no attention to the examination of urine during the past five years, by the new methods that have been introduced in that time—and of such there are too many—Dr. Tyson's book will be a revelation and a great boon. With it and its proper companion volume, Ralfe's "Kidney Diseases," and a third, now in manuscript form and soon to be announced in these columns, a physician will be thoroughly equipped for the investigation of abnormal conditions of the urine and kidneys, and for their proper medical treatment—at least as far as the present state of our knowledge has thrown light on the subject.

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION.

Membership.—Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member. He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate. As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not. Payment of annual dues entitles him to receive the weekly Journal of the Association for one year.

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society. They pay five dollars annually thereafter, when notified by the Treasurer. Members by application can join the Association at any time, and they receive regularly the weekly Journal.

When Dues are Payable.—The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter. The payment entitles the member to receive the Journal for one year from the following July. Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive.

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day. Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association.

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all* *payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia.*

Deaths.—When a member of the Association, who is in regular receipt of the Journal, dies, his family or other representatives are requested to inform the Treasurer at once of the fact.

Payment of Dues for Previous Years.—As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association.

Transactions of the Association.—These annual volumes, thirty three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices. The Index to these volumes will be forwarded on receipt of *One Dollar*. An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce.

Richard J. Dunglison, M.D., *Treasurer*,
Lock Box 1274, Philadelphia, Pa.

MISCELLANEOUS

Ohio State Sanitary Association.—The third annual meeting of this Association will be held in Columbus on February 24 and 25, 1886. There are good prospects for an unusually interesting meeting.

Cremation in Paris.—The Municipality of Paris has recently decided to erect a crematory at Père Lachaise Cemetery, and the plans have already been accepted. The expense of cremation must not exceed fifteen francs ($3.00), and the time required for combustion two hours. The erection of a suitable building for the urns or other funeral vases containing the ashes of dead relatives is contemplated.

Sir J. Crichton Browne.—Those who have read Dr. Browne's valuable contributions to psychological literature, will be interested in knowing that the honor of Knighthood has been recently conferred upon him.

Prizes of the Spanish Medico Chirurgical Academy.—The Spanish Medico Chirurgical Academy has published the following programme of themes for prizes to be given at next year's competition. The essays may be written in English, and must be sent in by the middle of September next, accompanied by a sealed packet containing the author's name and address, a motto being endorsed on the envelope similar to that inscribed on the essay. 1. Prize given by the Academy, £10. What modifications has the panspermist theory produced in the treatment of internal diseases which are known, or suspected, to be of a parasitic nature? 2. Prize given by Senor Morales, £30. Critical examination of the progress made in operations on bones.

Finger-Marks and Murder.—Our Paris correspondent forwards particulars of a remarkable trial for murder held recently at Rodez, in the south of France, where a self accuser was proved to be innocent, and the true criminal detected by medical evidence. Last August, a woman, named Melanie Vieu, went to register the death of a child, which she had wrapped up in her apron. The registrar examined the child, as is customary, and observed finger-marks on its throat. The mother then declared that she had strangled her infant. She was sent to prison, but Dr. Desmont, who had been directed to examine the body of the child, stated that it had certainly been strangled, but not by its mother. Her hand was more delicately formed than that of the murderer, which had left its impression on the child's neck. The fingers of the guilty party must have been short and thick, the index finger being unusually short, and apparently devoid of a nail, defects which the witness indicated as valuable clues for the discovery of the murderer. Melanie Vieu finally admitted that the murderer was a man called Bonuet and that she was his servant. The accused was arrested, and his index finger was found to be one centimetre shorter than the average length of that member, and its nail had been destroyed by accident or disease. Bonuet was sentenced to six years' imprisonment.—*British Medical Journal*, Jan. 9, 1886.

Merritt Hurst, M.D., late of Sweetwater, Menard Co., Illinois, died suddenly of disease of heart (supposed) on October 4, 1885. Dr. Hurst was born in Washington County, Ky., on July 14, 1840, and removed with his family to Illinois in September, 1849. He served as a private soldier and as first Lieutenant in the Civil War, and at its close began the study of medicine with Dr. A. L. Currier, of Sweetwater, Illinois. He graduated from Rush Medical College, Chicago, in 1868, and at once began the practice of medicine in Sweetwater. His life from that time was devoted to his profession. He was brotherly in his professional work, and left a community besides his relatives to mourn his loss. He was a member of the local medical society, and of the Illinois State Medical Society. He became a member of the American Medical Association at its last meeting.

LUPUS ERYTHEMATOSUS

A Clinical Lecture Delivered at the College of Physicians and Surgeons of Chicago

BY HENRY J REYNOLDS, M D ,
PROFESSOR OF DISEASES OF THE SKIN IN THE COLLEGE

I will to day, gentlemen, invite your attention to the study of a comparatively rare form of disease, the case before us being the first of the kind presented at our clinic now for about a year, during which time we have had, perhaps, almost a thousand different cases of skin disease presented for treatment Though, to a certain extent, similar in character, and bearing a somewhat similar name to lupus vulgaris, upon a case of which, you will recollect, we made the scraping operation a few days ago, it should, I think, be regarded as an entirely separate and distinct affection, and is at the present day usually so considered In this disease and lupus vulgaris we never find the one merging into the other, nor do we find intermediate forms between the two diseases, as in the various forms (so called) of eczema and acne, for example, they always remain distinct from first to last The name of this disease to which I refer and of which I have a case for your inspection, which illustrates the disease in a most typical manner, is *lupus erythematosus*

Before directing your attention to this individual case, however, let us first get a general idea of what the symptoms and characteristics of lupus erythematosus are According to the classification we have adopted the disease belongs to the class known as "new growths," and, as the name implies, it presents an erythematous or reddish appearance It is found chiefly upon the face, generally makes its appearance from adult to middle life, and is more frequent in females than in males There is not necessarily, so far as we are capable of discerning, any appreciable constitutional disturbance It is an extremely chronic affection, lasting sometimes for years, or even throughout life, in spite of treatment The sites of preference are the cheeks or nose, the eyelids, forehead, ears, scalp, and more rarely the hands and feet Occurring upon the face it tends to involve both sides symmetrically The disease generally first makes its appearance as a small pea sized slightly elevated, brownish red macule upon the cheek or nose In due process of time, as the original patch progresses, new spots are apt to appear, first, perhaps, upon the opposite cheek, then the nose, forehead, scalp, etc We rarely find less than two patches, and sometimes they are numerous, and when the case is first seen by the physician they may represent all stages of progress of the disease These patches remain constantly about the same, except that they gradually spread by peripheral extension, the border of which is well defined and slightly raised As the patch spreads peripherally the central part shows less activity, and becomes atrophied and depressed, giving, as in ringworm, the appearance as if clearing in the centre If untreated, each patch is seen to be covered with yellowish white, firmly adherent scales, upon removal of which, they will be found sometimes to project down into the sebaceous ducts There is no moisture or discharge in the disease from first to last, and the subjective sensation is that of occasional or constant slight itching, for the relief of which the part is more rubbed than scratched If the disease progress favorably it is followed by a smooth, uniform scar

The history of this case is as follows W M , æt 17, born in this country, father Italian, mother Irish, and both healthy Patient is at present otherwise healthy The eruption first made its appearance a year ago, as a slightly elevated, brownish red macule about three-quarters of an inch below the right eye; soon another similar patch appeared at an almost corresponding point on the opposite side, and later other patches appeared about each cheek, on left ear, etc , till we now find about half a dozen of such patches The size of the patches representing their order of evolution, you will notice now, as he passes around among you, that the one below the right eye, which has now reached an inch in diameter, was the first to appear, the one on the left side the next, and so on, the smallest patches representing the disease as it first appears You will notice that perhaps the most striking characteristic is the redness or erythematous condition, from which the disease has received its name, that it is confined to the face, the favorite site for the disease, that the subject is neither in childhood nor old age when attacked, that it is extremely chronic, slow, and free from exacerbations in its progress, and that we have an occasional cropping out of a new patch with a similar behavior We also find in this case the characteristic tendency to symmetrical distribution You will also observe that each of these patches is accurately defined, with a slightly raised, active border, and a tendency to clear in the centre, that they spread by peripheral extension, and are circular or oval in outline You will see, also, that each patch is covered by the characteristic yellowish, firmly adherent scales, and, lastly, that the disease is entirely free from moisture or discharge, and that there is evidence of a tendency to atrophy, depression and scarring in the centre, the case thus, as you see, presenting all the characteristics of the disease

Diagnosis —Now, without going further, the characteristics referred to in this case alone, collectively considered, are sufficient to base a diagnosis upon, the same *combination* of symptoms occurring in no other disease As many other skin diseases display some of these same symptoms, however, let us see what they are and exclude them Among them may be mentioned lupus vulgaris ringworm, eczema, psoriasis, and superficial epithelioma

Lupus vulgaris may be excluded by its first appearing, usually, in childhood It is more nodular and lacks symmetry of distribution, is more destructive, involves deeper tissues, ulcerates, etc

In *ringworm* of the face there is no tendency to symmetrical distribution, it is not so chronic, it lacks the characteristic yellowish, firmly adherent scales, they being loose and furfuraceous, the border is not so active and raised, it pales more on pressure, and we further have a history of contagion, discovery of the parasite with the microscope and no scar as a relic of the disease

In *eczema* we have a history of moisture, greater itching, it is more acute, the margins are not well defined, it is not limited so constantly and continuously to one location, there is not necessarily a raised margin and a clearing in the centre, the scales are not so adherent, and there is no scarring as a relic of the disease

In *psoriasis* the almost pathognomonic, white, silvery scales, which leave, upon removal, the characteristic red, bleeding patch, together with its usually general distribution, would alone exclude that disease

Superficial epithelioma is a disease of old age In this disease we have excoriation, moisture, brown crusting, ulceration, greater destruction and lack of symmetry

It will be seen, therefore, that each of these diseases is possessed of numerous characteristics that we do not find in the case under consideration, and we therefore thus exclude them

As to the etiology of the disease nothing is definitely known, some regarding it as of scrofulous origin, others as sebaceous, and others as having no connection with either

Treatment —Various remedies have been recommended for internal administration, such as iodine, iodoform, arsenic etc, as having a special influence over the disease There being no special constitutional disturbance, however, in this disease, or if any, its exact nature not being definitely understood, the treatment, to be intelligently applied, must be mainly local There being, however, such an intimate relation existing between the various organs and structures of the body, the one being therefore so dependent upon the other, any constitutional impairment naturally tends to prolong, if not to aggravate, most local diseased conditions, no matter how remote, and should therefore be sought out and rectified by proper constitutional measures

As to local treatment, inasmuch as we find a perverted nutrition in the diseased part, giving rise to new growth, a deposit of inflammatory exudate, etc, the rational inference would be, that such topical applications as tend to increase the physiological afflux of blood to the part, and thereby increase or change in character the nutrition of the involved structures, promote absorption of deposited material, etc, would be indicated, and to this end are used certain stimulants, irritants, etc, among which may be mentioned the daily application of hot water, rubbing in of green soap, application of iodine, chrysarobin, pyrogallic acid, sulphur, mercury, cantharides, etc, in various forms and combinations, as results seem to indicate In this case we will order, for the present, the parts bathed every night with hot water, then wiped dry and green soap rubbed in to remain for the night In the morning the parts will be again bathed and cleansed with hot water, and fine impalpable boracic acid be applied for the day, morning and noon say, the same process to be repeated every day If this set up too much irritation, the treatment must be changed from time to time and milder and more soothing measures be applied, as for instance, a drachm of sulphur to an ounce of lard or rose water ointment at night instead of the green soap

MUTUAL PROTECTION AGAINST BLACKMAIL[1]

BY E J DOERING, M D,

OF CHICAGO

Among the many trials which physicians have to encounter in the practice of their profession, is the ever existing liability of being blackmailed This may either assume the more frequent form of a so called malpractice suit, or the relatively less frequent charge of a criminal assault, according to the viciousness of the complainant It is undoubtedly a fact that such suits against physicians are on the increase The New York *Medical Record* has reported a large number in the course of the past year, and a glance over the Court-record in this city will prove the correctness of my assertion, as far as Chicago is concerned Every city is overrun with petty lawyers, who have little or nothing to do, and are always willing to undertake any suit whatever if there is the least prospect of getting something out of the defendant From what I have learned since investigating this matter, I am convinced that many of these blackmail schemes are settled before being made public Many a physician has preferred the payment of one or two hundred dollars rather than incur the publicity, the loss of time, and the endless expense of a lawsuit Again, the average jury, composed as a rule of the vulgar and illiterate, will always have a strong leaning towards the complainant and against the defendant, as physicians are popularly supposed to be capitalists Who, then, can blame a brother practitioner if, with all these facts staring in his face, he prefers being robbed by paying the blackmailer a stipulated sum rather than go to law?

---

[1] Read before the Chicago Medical Society January 18 1886

In justice to myself, I desire to state that personally I have never been sued, or threatened with a suit, and as I do not practice surgery in any of its branches, I consider myself comparatively safe It is therefore not from any motive of selfish interest, but from a sincere regard for the welfare of my professional brethren, that I desire to submit to your consideration the advisability of forming an association for the mutual protection of physicians against blackmailing suits of all kinds, arising from their relations as members of the profession My plan is to form an association composed of about two or three hundred members of the regular profession, all of whom shall be of acknowledged ability, possessing a good moral character, and standing well in the community Said association to employ one of the prominent law firms by the year, to furnish the members such legal advice as they may desire, and defend any suit arising against the members in the discharge of their professional duties From correspondence with lawyers, I find that an annual due of five dollars for a membership of two hundred would suffice to cover the expense An initiation fee of five dollars would create a sufficient fund for court expenses It is not necessary to enter into further details which can be easily arranged if it be desired to form such an association It is my firm belief that such an association would be a power in *preventing* suits being brought against its members Let it be known that the individual physician is backed by the financial and moral support of a few hundred of the best physicians, and aided by the best legal talent obtainable and he will be let severely alone by the dregs of society who constitute, almost without exception, the blackmailing element in our professional life

There is only one possible objection, it seems to me, which can be raised against such an association and that is, whether the fact of being a member of such a body would not prejudice the jury against the physician As this is a legal point, I have consulted several lawyers about the matter, and with but one exception they agreed that no such objection could be raised, provided the scope of the association would be as outlined in one of the legal opinions which I shall read later I do not know of the existence of such an association as the one proposed, in any other city, but I find the principle of mutual protection has been carried out recently by the New York County Medical Society From a report of an adjourned annual meeting of that Society, held November 23d, 1885, I quote as follows "The comitia minora recommend that the Society request Drs A E M and A S Purdy, defendants in the case of Brown versus Purdy, to appeal, the jury having brought in a verdict of $500, and also that the sum of $500, if necessary, be appropriated to aid in the proceeding" The Drs Purdy reported what they believed a case of varioloid The Health Board sent an inspector, who saw the patient, and the Board ordered a removal to the Small pox Hospital The plaintiff remained there a short time and was discharged, and subsequently brought suit for damages against the defendants with the plea that she did *not* have varioloid On motion of Dr Agnew, the recommendation was adopted

I desire now to submit to you some correspondence with reference to the proposed association Dr Wm H Byford writes as follows

Dear Doctor —Your project of forming a physicians' mutual protective association, I hope will be successful One of the greatest incentives to blackmail medical men is a fact well known, *i e*, medical men are not united There are some among us who think it very much to their interest to destroy a rival, by encouraging malpractice suits A powerful association of the kind you propose would prevent these or other viciously disposed persons from doing the harm they now sometimes do

(Signed) W H BYFORD

Our President, Dr Parkes, writes as follows

Dear Doctor —Your letter of to day was duly received and the contents carefully read I think, Doctor, the association you contemplate forming is greatly needed I am heartily in accord with you and will contribute whatever is within my power for its advancement

(Signed) CHAS T PARKES

Dr D R Brower writes as follows

Dear Doctor —Yours of this date to hand I earnestly endorse your mutual protective association It will be, as you predict, a means of drawing closer together the members of our profession, and of protection against the vilest of all members of society, the blackmailers

(Signed) D R BROWER

The following extracts are from a letter of Dr B Bettmann As will be remembered, the doctor was sued by a charity patient, who did not even have the shadow of a case against him "A heart rending reference by claimant's counsel to her old age, infirmities and poverty, had the desired effect The jury, after five hours' deliberation, brought in a verdict for plaintiff, fixing the damages at $4480 This unjust verdict was set aside by the Judge, and a new trial was granted, which took place several months later, and the case dismissed The plaintiff took a non suit and recommenced hostilities in the shape of a new suit for $25,000, which, by order of the Judge, was stricken off the calendar The expenses incurred by these trials amounted to $250 The annoyance and mental strain I underwent are beyond the comprehension of those who have not been placed in a similar unfortunate position I heartily recommend the formation of a physicians' protective union, which should be represented by an able lawyer, chosen by a committee I also would suggest the appointment of an Advisory Board, composed of two prominent representatives of each of the special branches of medicine The duties of such a counsel would be to thoroughly investigate every malpractice suit brought against a member of the union, and to assist in every possible manner to secure justice "

(Signed) BOERNE BETTMANN

Dr J H Etheridge states his opinion as follows, after briefly referring to an unsuccessful attempt, several months ago, to blackmail him "I am heartily in favor of organizing a physicians' mutual protective association against malpractice suits The existence of such an organization would deter many a person from beginning suits, when it is once understood that physicians are organized and possessed of funds and an attorney who means business ' The careers of many struggling young physicians would oftentimes be assured, were they only fortified and upheld by such an association I heartily endorse your efforts in this direction, and shall be pleased to cooperate with you in any capacity "

(Signed) J H ETHERIDGE

Dr S C DeVeny informs me that a recent most outrageous blackmailing scheme has cost him to date $800, which is small, however, compared to the loss of time and the mental distress he has been subjected to The doctor also is in favor of a protective association

The following letter is from Dr Plymmon S Hayes

Dear Doctor —In regard to my malpractice suits—for the case was tried twice—I paid my lawyers and short-hand reporters in round numbers eleven hundred dollars Each trial consumed about four days In addition to this I spent nearly one week in coaching my lawyers on the medical aspects of the case The trial came at a time when I could ill afford the expense I think it will be best to form an association of physicians and employ an attorney by the year, for the following reasons *First*, the lawyer should have some knowledge of medicine, and after a trial or two his competency could be proven, *second*, the attorney would soon become posted in regard to the medical witnesses, and in any given case would know who of the physicians to call, *third*, I believe that this plan would be cheaper in the end If the defendant in a malpractice suit desires another attorney as an assistant to the one furnished by the association, let him hire the attorney at his own expense If an attorney were employed by the year he could be consulted at any time by the members of the association in case they feared a suit, and thus have legal advice from the beginning

(Signed) PLYMMON S HAYES

Dr E L Holmes writes as follows

Dear Doctor —I would gladly take any measures for protection against malpractice suits that would really protect Would not the fact of belonging to such an organization as you mention, be a disadvantage to a physician brought to trial before a jury? Would the jury not be prejudiced against such a physician as, I believe, it always is against one who attempts to fortify himself by securing a written agreement from the patient that he will be satisfied with the result of an operation or treatment? The jury have always, as far as I know, turned upon the physician with the accusation that he has guarded himself, or attempts to do so, and then neglect his patient as much as he chooses If a considerable number of our friends have confidence in the plan, and it has been in successful operation in other places, I see no reason why I should not be willing to join the organization I should wish to discuss the question in all its aspects

(Signed) E L HOLMES

The following letter is from Dr F C Hotz

Dear Doctor —I have had a little experience in malpractice suits, having been sued two years ago My attendance in court did not extend, all in all, over two hours, but how much time I spent with my attorney in preparing for the case I cannot say The case was dropped by the plaintiff after his witnesses had testified, but it cost me $250, actual cash expenses As to the forming of an association, I have some doubts as to its practicability These suits are not brought against the association, but against the physician himself They are, therefore, a very personal matter, and it might be that the lawyer chosen by the association might not be the one whom the prosecuted doctor would choose to protect his personal interest You know it is with lawyers like physicians, largely a question of confidence, and I, at least, if I should be unfortunate enough to have another malpractice suit, should wish to employ only the attorney of my own choice

(Signed) F C HOTZ

Dr H A Johnson writes as follows

Dear Doctor —I have thought over your proposed mutual protective association I may be mistaken in my estimate of the needs of such an organization, but it seems to me that these needs are small, that it would hardly justify the labor and expense of the machinery I do not hear of suits for malpractice very often, and possibly I am so far out of the way, I mean out of the general practice, that I have overlooked them (Signed) H A JOHNSON

Dr E Andrews states his opinion as follows

Dear Doctor —The object is a worthy one Like everything else, the plan involves some difficulties The fact of a powerful club being known to exist for defence, like an old sword, cuts two ways It tends to prevent suits on the one hand, but if one comes actually to trial, it will prejudice the jury against the defendant, just as corporations do Some of the members may not wish to use the attorney selected by the club, and as a matter of fact, such a body will rarely succeed in selecting the best man I am not clear at this moment how these evils can be best obviated, but the whole matter will require very careful study and adjustment

(Signed) E ANDREWS

Dr D A K Steele, whose advice and assistance have been sought in several more recent suits, writes as follows

Dear Doctor —With proper restrictions and safeguards I am decidedly in favor of a physicians' mutual protective association Physicians and surgeons are peculiarly liable to be threatened and harassed, or actually bled, by blackmailers In union there is strength, and a combined effort to resist an attack upon the reputation or skill of a member by an association of the profession would do much towards lessening the frequency of malpractice suits Most of these cases are taken by lawyers upon a contingent fee, and not infrequently urged upon the patient by the assurance that it will not cost him anything, and that the lawyer will give him half of whatever he recovers, or of the amount for which the unfortunate physician compromises rather than bear the expense and worry of a suit If these shysters know that the physician is a member of a mutual protective association, morally and financially sustained by the general profession and defended by a first class attorney who will fight the case from court to court, the contingent fee will seem so distant that these fellows will think twice before boldly walking into a doctor's office and demanding an immediate settlement or threatening a suit for malpractice I would suggest the appointment of an Advisory Board, which in a quiet way should investigate every case before official action is taken by the society, so that in the very rare event of a member of the association being actually guilty of malpractice, he could be advised to compromise his suit

(Signed) D A K Steele

Dr Chas Warrington Earle sends me the following letter

Dear Doctor —I am in receipt of your letter relative to your paper regarding blackmailing I am heartily in spmpathy with the movement, although it may be necessary for us to steer clear of some legal dangers

It appears to me that the greatest trouble will be in the selection of members There are some men in the profession who by their actions invite suits of malpractice, and there are others who encourage suits by their unwise conversations with the people These are the men whom we must seek to exclude

(Signed) Chas Warrington Earle

Finally, I desire to submit a legal opinion on the principal objection raised by my correspondents, viz what effect a membership in such an Association would have on the jury

Munn and Wheeler, the well known criminal lawyers, give the following opinion

Dear Sir —Referring to the matter of a physicians' protective society, the object of which shall be the mutual protection and defense of its members in any suits which may be brought against them in a professional capacity, we desire to say that in our opinion such an organization would be an excellent one, that the idea is an idea embodying not only good common sense, but also the best business principles and foresight It is a well known fact that by far the greater number of the suits brought against physicians in their professional capacity are without any good foundation, being for the greater part mere blackmailing schemes The defense of such suits by an individual is exceedingly burdensome and expensive The members of such an organization as the one in question might, by the payment of a small amount yearly, each secure efficient legal talent to attend to all such cases We do not believe that the fact of membership in such a society would at all prejudice a jury, nor could it, as a matter of law, be properly brought before a jury (Signed)

Munn & Wheeler,
Counselors at-Law

Mr O H Horton, of the firm of Horton, Hoyne and Saunders, one of the prominent lawyers of this city, gives the following opinion

Dear Sir —I see no reason why you may not legally organize and maintain a society of members of your profession for mutual benefit and protection, as suggested by you The practical question has suggested itself to me of the effect of such an organization in court upon a jury, in case one of its members was being prosecuted Strictly speaking, the fact that the defendant was a member of such a society would not be competent evidence It would, however, doubtless get into the case, if the attorney for the prosecution desired to have it appear In most, if not all, of the class of cases to which you refer, it is necessary for a physician to call other physicians as witnesses In that event such witnesses could be asked if they were not members of such a society and therefore interested in the suit, etc That would bring out all the facts as to there being such an organization But, as I understand the matter from you, it is not the purpose to have the society pay any judgments, if any be recovered against one of its members, but to defray the expenses, that is, pay the costs of making a defense, including attorney fees I would, therefore, suggest that in specifying the objects of the association, you should include not only the protection of its members, but of their patrons and the public as well, that is, that the professional secrets and confidence reposed in the physician by his patrons should be protected from being made public in case it was sought in any manner to compel the physician to reveal such confidential communications, etc In other words, make the organization as much for the protection of the employers of the physicians as the physicians themselves I think that that would remove all practical objection to the organization, so far as the effect in court upon the trial of a case is concerned

(Signed) O H Horton

This finishes the correspondence, which in itself is so complete that I have nothing to add I earnestly request every gentleman present to night to state his opinion, whether or no he is in favor of forming such an association as the one proposed The time at my disposal is very limited, but if I receive enough support to encourage the formation of a protective union, I promise to do all in my power to make it a success I believe such an association to be entirely practicable, that it will be a power for good, that it can do us no harm, that it will draw us closer together as a profession, that it will be a great satisfaction to one assailed by misfortune to have the sympathy and support of his fellow practitioners—that, in short, it will favor the principles of a common brotherhood, viz equality, harmony, justice and unity

A CASE OF PROLONGED GESTATION

BY SAMUEL K JACKSON, M D ,
OF NORFOLK VA

In May, 1884, I was called to Mrs T , æt 30, who was suffering with severe dysmenorrhœa She had not borne a living child for thirteen years, but had had several abortions, certainly two within the past four or five years, since the last of which she had menstruated regularly, but with increasing pain, as she reports, each month, until the period mentioned, when it became so violent as to require medical aid Bridging over this attack with palliatives, I deferred an examination into its cause until after the menstrual flow had ceased, when I found almost an entire occlusion of the cervical canal, not so much from engorgement or hyperæmia, as the result of an inflammatory condition, which probably had existed for some time, and still existed to some extent Devoting attention more particularly to this during the early part of the month, I delayed any attempt at dilatation until the approach of the next menstrual period The dilatation was successfully, though with difficulty, effected by the introduction of a piece of sea tangle just two days before the expected catamenial flow, with the effect of entirely preventing another attack of dysmenorrhœa, and she has not ceased to menstruate since that time with ease and regularity

But notwithstanding this want of interruption in the menses, she presented symptoms which during the following month of September rendered it probable that conception had taken place some two months before, possibly near to the July menstruation During the month of October there was considerable abdominal enlargement, of about the shape of three months gestation On the 22d of October she imagined that she "felt it," but in this she was evidently mistaken, as she discovered afterwards by very distinct sensations of "quickening" occurring when she was on a visit to Baltimore on the 9th of December She had been threatened with abortion in October, and during the following month it was with great difficulty prevented

On her return from Baltimore towards the close of this month (December), a stethoscopic examination failed to discover the beating of the fœtal heart, but this unmistakable sign presented itself on the next examination, during the early part of January, 1885 It was perceived again in the latter part of this month Up to the time of this revelation there was considerable doubt as to the existence of pregnancy, several of the most reliable signs being wanting For instance there was no cessation of the menses, and there was no shortening of the cervix (nor was there up to the finale of the case) But all doubt was removed by recognizing the fœtal heart, and as it was perceptible at this period it was evident that conception had occurred very near to the time it was first suspected

These decided proofs, together with her own sensations and perception of the motions of the fœtus, had the effect of allaying much nervousness and anxiety, which had existed through the long period of doubt, and she immediately set about preparations for the approaching accouchment, which was confidently expected about the 1st of May The probability of its occurring at this time obliged me to relinquish the long cherished purpose of attending the New Orleans meeting of the American Medical Association About the 1st of March her mother, who resided in Baltimore, importuned her to come home to be confined A struggle between the desire to be with her parent and that to remain with her physician was quieted by my promising to go to Baltimore to attend her on the interesting occasion, and she left me early in April, with the expectation of seeing me in a month's time Her letters to me from Baltimore evinced anxiety lest I should not get to her on time As Tuesday, the 28th of April, was the earliest calculated upon, I reached her on the morning of that day I found her very large and clumsy, and in hourly expectation, as she said she had occasional premonitory pains

Spending as much time with her as possible, I could perceive no signs of approaching parturition, but on my visit on Thursday morning (April 30) she told me that she had violent pains during the previous night, and begged me not to leave her again To quiet her anxiety I remained at her mother's house, and after sleeping all night was surprised on awaking that I had not been aroused

As I was spending so much time to no purpose I insisted upon an examination, to determine what the prospect might be of the delivery coming on within a reasonable time To my great surprise I found the same elongated cervix which had obscured the case from the beginning, and no signs by which I might calculate upon a delivery within a considerable time, and therefore I was reluctantly obliged to announce to her my determination to turn her over to another physician and return home Her mother's family physician, Dr Geo R Graham, was selected, to whom I gave a history of the case from the beginning, told him of my doubts and fears, and finally of the conditions which influenced my opinion, and left him in charge of the case I was gratified to learn by a letter from Dr G that his diagnosis agreed with mine, and that he had been able to recognize the fœtal heart, but subsequently, owing to the reluctance of the uterus to relieve itself of the burden, he very reasonably inferred that it must be an extra-uterine pregnancy From the accounts given me of the progress—or rather the want of progress—of the case, I also was inclined to entertain this fear

The patient became so nervous and uneasy about her condition, increased by the importunity of friends, she concluded to consult a physician in Baltimore whose talents and experience have won for him a high position in the profession A partial examination at his office inclined him to doubt the existence of pregnancy and to suspect a tumor, but, as reported to me, he refrained from giving that as his opinion until he could be satisfied by a more thorough examination, which was made by himself and a specialist in that department in the presence of Dr Graham These gentlemen adhered to the opinion previously formed, and diagnosed that the abdominal enlarge ment was due not to a pregnancy, but to a fibro-cystic temor of the right ovary, and advised an operation. From this opinion Dr. Graham dissented, as will be seen by his letter to me of August 25, from which I give the following extracts in order to furnish a history of the case while the patient was under his care.

BALTIMORE, Aug. 25, 1885.

DR. S. K. JACKSON:

My Dear Sir:—In reply to your letter I will state that Dr. ——'s diagnosis was "Fibro-cystic tumor of the right ovary." But I am not at all convinced that he is right, though it may seem presumptious in me, with my limited experience, to pit my judgment against his. Having ventured my opinion, it is but fair that I should give reasons for the faith that is in me.

On the day following my interview with you at my office (May 1), I was called to see Mrs. T. and found her suffering with what appeared to be severe and well defined labor pains. I was informed that there was a "show." The pains were regular, at intervals of about five minutes. I made a digital examination, and discovered what I expected from information obtained from you, the rigid and elongated cervix. Retaining my fingers during the next pain I was surprised to feel something hard and apparently round pressed downward by the force of the contraction, which differed from anything I had ever felt under similar circumstances. I concluded that this was the body of the uterus, for I could outline the fundus very distinctly. I pronounced that the case was one of extra-uterine conception, and that the child could not be born by the natural means. My rash announcement had the effect of causing a nervous attack, which culminated in a severe chill. This caused me to modify my statement and express a hope that I might be mistaken, and I left her promising to make a thorough examination the next day, on which occasion I thought I made out the extremities of the fœtus lying in a transverse position in the abdominal cavity. I distinctly felt movements, which, however, may have been caused by contraction of the abdominal muscles. By auscultation I am as sure as a man can be under the circumstances, that I could detect the fœtal heart sounds. I was strengthened in this belief by your statement that you also had heard the fœtal heart. The pains were still present, but under the influence of the drugs had abated in frequency and severity. There was considerable hæmorrhage, but no mucus. By digital examination I could make out the whole uterus as I did the night before. Feeling that as the case had gone to full term, I was justified in sounding the uterus, I attempted to insert my speculum, but the patient exhibited such evidences of nervousness and distress, I was obliged to desist from this crucial test until another opportunity, which unfortunately was never afforded me. The next day pain and hæmorrhage had ceased. I gave a guarded opinion, and counseled waiting.

Four weeks later the pain and hæmorrhage were renewed, but not so severe. Palpation and digital examination gave same results as before, but I was not permitted to examine per speculum. I noticed that there was a decided change in the shape of the abdoment, the enlargement having descended. The patient declined to permit me to take active measures to ascertain her true condition, so I was reluctantly obliged to again wait and watch.

Four weeks later the pains were again renewed but still milder. Her husband being in town he prevailed on her to consult Dr. ——, which she did. On examining her at his office he pronounced it an ovarian tumor. Subsequently, at my request, and after hearing my statement, he reexamined her, but did not change his opinion as at first expressed, although he could not cite an instance where an ovarian tumor had grown so rapidly in eleven months, and then suddenly ceased growing, and become much diminished in size in the course of one month. Such is not the history of ovarian tumors. I confess there are many points which tend to confirm Dr. ——'s diagnosis, and also his vast experience must be taken into consideration. But I will not be convinced that he is right until I have the evidence of a competent witness who has seen the tumor after removal. I would be much pleased to have your opinion of the case and be kept informed of its progress. I have taken great interest in it.

Very truly yours,
GEO. R. GRAHAM, M. D.
136 Columbia Ave., Baltimore, Md.

The patient refused to submit to an operation for fear she would not survive it, and determined to return home to Norfolk, which she did about the latter part of July. Being summoned to her, I found her excessively depressed in spirits, and with her mind made up that she had not long to live. Supposing the Baltimore diagnosis correct, it was difficult for me to find for her one word of cheer, for I could only comfort her by endeavoring to assure her that it might be years before it destroyed life. She argued that it must be rapid, as it had already grown to its present large size in so short a time. She importuned me to know if there was nothing to be done that might arrest its growth. I really thought there was nothing upon which we could build any hope, but, in order to occupy her mind and feed her hope, I told her I intended to try the effects of electricity, but before doing so, wished to make another examination, as I had not made one since I left her in Baltimore about the 1st of May. I was utterly surprised when this exploration revealed the presence of a fœtus. It was lying transversely across the abdomen, and so low as to force me to the opinion that it must be outside of and in front of the uterus. The head and buttocks were certainly distinguished and located, and so positive was my diagnosis that I declined to interfere with it and determined to let natur take its course. Just at this time the journals brought me the report of Angus McDonald's case of impregnation of one horn of a bicornual uterus, and there were so many points of resemblance to this case, I thought it would be a comfort to her to read it and to learn of its fortunate result, and at the same time to know that it was possible for even learned and experienced physicians to make mistakes in diagnosis. I found that I had not miscalculated its effects, for the next month (August) was spent in comparative freedom from anxiety. She would imagine that she sometimes felt the motions of the fœtus, but this I doubted, for I had become impressed with the idea that it was either a case like McDonald's, though in a different position, or was extra uterine, in either case most probably not living, as she was now certainly in her thirteenth and possibly her fourteenth month of pregnancy.

My surprise may be imagined when, on the 7th day of September, she gave birth to a living child, not very large (eight pounds), but certainly old looking. The bones of the head were very hard, but fortunately well lapped at the sutures. It is to-day (November 30) just twelve weeks old, but it looks double that age.

I have given this full and, what may seem, prolix history of this case on account of its anomalous character being unlike any that had occurred in my experience, or of which I have seen any record. In Angus McDonald's case, which has been mentioned (published in the *New York Medical Abstract* in May, 1885, page 168, from the *Edinburgh Medical Journal*, April, 1885), the fœtus went to full term and probably a little beyond it (to ten months), after which time it died *in utero* and was retained twelve months longer without decomposition, and the same mistake in diagnosis was made as in the case herein reported, which perhaps was more excusable, as the fœtus was not living, and had not been for twelve months. In my case the fœtus was living and carried at least four months beyond term. The only doubt that could be entertained by any one as to the correctness of this calculation was as regards the September diagnosis, of which, though I could not be positive at the time on account of the absence of some reliable signs the subsequent history furnishes abundant proof. The quickening unquestionably occurred not later than December 9, just nine months before delivery, the heart sounds were distinguished just eight months before that event, and probably ought to have been detected earlier.

If I have left any points in this interesting case at all obscure, I shall be glad to reply to any inquiries necessary to clear them up.

140 Freemason St., Norfolk, Va.

PUNCTURE OF THE LIVER FOR (1) HEPATIC INFLAMMATION, (2) ABSCESS, (3) HYDATIDS

BY EDWARD HORNIBROOKE, M.D.,

OF CHEROKEE, IOWA.

Hepatic Inflammation—Puncture of Liver, Recovery.—Edward Roach, æt. 35, farmer. Family history good. When he consulted me on July 1, 1876, he had all the symptoms of acute hepatitis. He was treated in the usual manner for three weeks, when a red, hardened, tender swelling made its appearance at the margin of the ribs. After poulticing and using the usual remedies for two weeks without alteration in the symptoms, it was decided, in consultation with Dr. Stoner, of Stratford, Ontario, to puncture with a trocar, after the method of Surgeon General Cameron, of the East India Army. A deep puncture was made, but no pus obtained. There was no shock resulting from the operation, and improvement commenced at once. The swelling subsided, the temperature fell from 102 on the day of operation to normal on the third day. He had fully recovered in four weeks.

No mention is made of this method of treatment in Bartholow's exhaustive article on diseases of the liver in Pepper's "System of Medicine."

Hepatic Abscess, Opening through the Lung, Puncture, Recovery.—Mrs. C. L. I., æt. 35, consulted me September 26, 1885. She had been under the care of other practitioners for eight weeks. She had the usual symptoms of hepatitis during the first four weeks of her illness. A swelling then appeared at the lower border of the ribs, which was said to have been soft and fluctuating. About two weeks before my visit she coughed up about two pints of horribly offensive pus, when the swelling and tenderness subsided. She continued to cough up enormous quantities of this pus—say one to two pints daily. In spite of treatment this continued without abatement till the 14th of October. Her strength was failing rapidly, and she and her friends became importunate to have something done to relieve her from the horrible taste and distress of coughing up this material. On October 14 it was decided, in consultation with Drs. Sherman and Burlingame, of Cherokee, to aspirate, with the largest needle, the lower part of the right lung, where, from the dulness of the percussion note and the other symptoms, we expected to find pus. None was withdrawn, and we then introduced the needle through the site of the original swelling. The needle was passed into the substance of the liver in several directions. A few drops of pus mixed with blood escaped, and the needle was found filled with blood and pus. It had been explained to the patient and her friends that this would probably be the result. The patient was under ether during the operation, and no shock appeared to result. The quantity of pus decreased day by day subsequently, the temperature fell to normal, the appetite increased, the odor of the sputa abated, and within a week she was convalescent. I saw this patient again on November 25. Her strength had increased, her appetite was good, and the amount expectorated was almost nil.

Does not the result of these two cases go to show that puncture of an inflamed liver sets up a new action and is directly curative in its effects, as had been argued, and I think proved by Surgeon General Cameron?

Hydatids of Liver, Puncture, Death.—On June 8, 1885, I was consulted by H. Boylan, æt. 55, who had been ill about one year, the most prominent symptoms being severe attacks of colic, want of appetite, great enlargement of liver, and gradually failing strength. A swelling on right side extended below the umbilicus, was hard, no fluctuation could be detected, and the lower margin well defined. On the left side there was also a large protuberance and well-marked sulcus and softness in the epigastrium.

The swelling on the left side was supposed to be the spleen No improvement resulted from medical treatment

On July 9, I punctured the liver in its most prominent part, just to the right and a little above the umbilicus No serum or pus was found, and as the patient was very weak and not under an anæsthetic I did not explore the liver so fully as I desired No pain or ill effects were experienced from the puncture He rallied for a few days and died suddenly on August 26

Autopsy eight hours after death, present Drs Sherman, Quirk, Meyers and Hornibrooke Heart and lungs normal The friends had stipulated that the head should not be opened The abdominal cavity contained a small quantity of serum The liver extended as low as the umbilicus and across the median line, filling the left hypochondrium and pressing against the spleen, which was of normal size and consistence The stomach was behind the liver which seemed hollowed out to receive it, and with the sulcus in front, gave the two parts somewhat the appearance of the old time physician's saddle bags, heavy and large at both ends and slender in the middle We could find no trace of the puncture which had been previously made The margin, especially near the epigastrium on the right side, was hard, the inferior surface concave The whole of the lower surface of the liver was studded with whitish, slightly yellowish, flattened vesicles (hydatid), filled with a whitish fluid Several hydatid cysts as large as a coffee cup were found in the substance of the liver, filled with a fluid similar in appearance to that found in ascites The gall bladder contained bile and we observed no obstruction to the duct

Cherokee, Dec 10, 1885

CORYZA, ITS CAUSES AND TREATMENT

BY GEO N MONETTE, M D,

OF NEW ORLEANS

This affection has hitherto been regarded as a disease of comparatively minor importance yet, latterly, owing to advances and improvements made in the modern method of treating processes, as well as the extravagant dissipation of the majority of the laity, as also the subsequent effect upon a constitution improperly developed physically, not being inured to the transitions of temperature by suitable clothing we find that the disease prevails almost universally becoming more prevalent in warm latitudes where hitherto, it was seldom prevalent. There has been, quite justifiably, an impression among the body politic, that a cold in the head (which is a decided misnomer) was nothing in entity but could be readily relieved, and permanently

Among the many features provocative of this malady, extraneous to hereditary influences, I am constrained to accredit the habit of smoking, as being the source of the majority of the most aggravated cases So many of the younger men mistake their nasal appendage for *smoke stacks*, that they essentially become victims to the relaxation subsequent to the stimulant influence of a steady stream of hot smoke through the nasal passages This relaxation ultimates in a species of hypertrophy of the Schneiderian mucous membrane, and of the continuity of the turbinated bones, where virtually exists the disease denominated catarrh In my practice, I have had numbers of cases under observation which I have denominated "*smoker's throats*," implicating the posterior fauces, palatine arches and walls, the uvula, the turbinate bones, the Eustachian ducts and the epiglottis and trachea The mucous surfaces were excoriated almost literally, the catarrhal phenomena were typically troublesome, and provoked an insatiable desire to clear the windpipe and owing to a decided narrowing of the canal (nasal), induced a form of dyspnœa which has been denominated nasal asthma The ingress of the volumetric *pressure* of air is far greater than the outlet at the posterior nares, due to an hypertrophied condition of the turbinate ossific vaults The excoriation undergoing cicatricial restitution ultimates in a pachydermatous condition, compromising the normal nasal secretions as also stillicidium, which indicates a fulness or thickened condition of the membrane, closing the *ductus ad nasum*

Atmospheric influences are most proverbially provocative, those extraneous to direct exposure, such as passing from heated to cold atmospheres, also after becoming superheated, then removing surplus clothing and having the action of the skin suddenly checked Dusty atmospheres especially, caused by rolling cotton bales, rice or coffee mills, lime kilns, shell roads, pikes, flouring mills, mop factories, enclosed saw-mills, grain elevators, and ship holds when being loaded with cotton or bulk grain Our shelled levee, with the slightest breeze, envelopes everything in a dense cloud All sorts of particles wafted promiscuously are potent irritants, first by such a quantity being inhaled and deposited upon the mucous surface, causes an acute secretion, and by a continuance or repeated attacks similarly entail a chronic exudative rhinitis which ultimates in an œdematous condition of the membrane, and finally implicating the nasal canal, and inducing really a form of acute osteitis or hypertrophy of the turbinate bones, which sometimes exfoliates and suppurates, and chronic ozœna results

Having enumerated various causes of this malady and having given, to some degree, the pathology of this annoying complication the treatment is next of vital importance Nasal douches without number have been directed against this anatomically delicate canal and with detriment ultimately Such are not beneficial, simply because of the difficulty of keeping the Schneiderian mucous membrane saturated (so to speak) with any medicament, and furthermore the forcible contact of the steady stream serves to enervate and ultimately to relax completely, from the subsequent engorgement. Vile irritant snuff compounds have been sold, and with no benefit Unscientific appliances have been manufactured, and recommended for use, directing the same upward instead of *horizontally*, to reach the imaginary locality of the disease

I greatly prefer the inhalation treatment, either by evaporated medicines, or by the insufflation of some emollient substances Astringents, strictly vegetable, are not indicated for permanent use I have found subnitrate of bismuth to be the most soothing, and absorbing the profuse nasal secretion relieves the irritable mucous membrane, when the defluxion is offensive, then a small quantity of iodoform combined with it deodorizes the discharge, which is removed by hawking The bismuth deodorizes the iodoform, and its peculiar odor is not perceptible after a short while My plan is to clear the canal, and inhale my powder only at night, retiring as much as will remain upon the end of a match My formula is

℞	Bismuth subnit	ʒj
	Iodoformi	ʒij
	M and pulv Sig —Locally	

This has never failed to relieve any case coming under my observation

MEDICAL PROGRESS

The Surgical, Physiological and Æsthetic Advantages of the Artificial Vitreous Body — Dr P H Mules read a paper on this subject at the last meeting of the British Medical Association Sympathetic ophthalmia, or disease of a sound eye, caused by injury to its fellow, was brought to the notice of the profession by Mackenzie, of Glasgow (*On Diseases of the Eye*, 1840) He referred to it as well known to his colleagues and himself, and, as the name implies, attributed it to nerve sympathy, or in modern terms, a "reflex neurosis" This theory held general acceptance until a very late period, and even now there are many believers in the sympathetic origin of the disease Be that as it may, a school has arisen which refers the disease to "bacteria" having its first point of localisation in the uveal tissue, there producing a specific uveitis with germs, "bacteroid bodies," capable of self-propulsion along the perineural lymph spaces of the first affected eye, across the chiasma, and down the lymph spaces of the sound eye, reproducing a similar affection, often with disastrous results Holding this view, I designed, for the prevention of sympathetic disease, or, as we now term it, "secondary septic ophthalmitis," the operation of "evisceration of the globe," on the lines hereinafter laid down, to be associated in suitable cases with the use of the "artificial vitreous body"

It is right here to state that the operation of "evisceration" has been occasionally practised by surgeons as an emergency-treatment, but the perfecting thereof, and the rules for its safe performance, were placed upon a secure basis by Dr Grafe, of Halle, and myself during the year 1884, working independently of each other To our illustrious countryman, Sir Joseph Lister, we are indebted for the antiseptic treatment which alone makes this operation feasible Perfect faith in the bacterial origin of this affection led me to the steps hereinafter named, for it was not enough to eviscerate the intra ocular contents, and leave only a small button of sclera on which to plant an artificial eye (immeasurably superior as it is to the operation of enucleation), and, following out the logical sequence, that total exemption from the dangers of sympathetic disease being assured by early removal of all the uvea, the introduction of a permanent hollow glass sphere within the denuded sclera could produce no ill effects, the result has fully realised the most sanguine expectations To attain this end, the following steps carried out with a scrupulous attention to detail, are necessary Any eye may be eviscerated, except such as are infected with tubercle, glioma, or any other known malignant growth Small stumps, when painful, can be opened, cleansed, bone or foreign bodies removed, and the pain and uneasiness disappear, leaving a smaller stump, but safe from danger to the sound eye, except in those instances where bacteroid bodies have travelled beyond the globe Even then it is a fair assumption that no more harm could possible accrue than if the stump was enucleated

The instruments necessary for the due performance of the operations are 1, a hand spray, 2, a siphon-tube of India rubber to flood the eye after or during operation, 3, an ample supply of solution of corrosive sublimate (1 to 1,000), 4, an eye speculum, 5, fixing and dressing forceps, two pairs, 6, a Grafe's knife, 7, a spoon to evacuate contents (Bunge, of Halle, has devised an instrument, but any scoop answers equally well), 8, needles threaded with chromicised catgut (fine size), 9, artificial vitreous bodies in assorted sizes, 10, dressings namely, iodoform, wood-wool pads in Lister's gauze, oiled silk, glycerine, boracic or sublimated bandages

The operation is divided into two parts The first part, complete in itself, is evisceration It is conducted as follows 1 Anæsthetise the patient 2 Use the hand spray, and thoroughly cleanse and disinfect the appendages with 1 to 1,000 solution of corrosive sublimate 3 Transfix and remove the front of the eye with a Grafe's knife at the corneo scleral margin, cutting round the conjunctiva first 4 Empty the contents of the globe in any way that is convenient, taking special care to remove the ciliary body and choroid, leaving a clean white sclera 5 With a thin India rubber tube (Inst 2), used siphon-wise, run the sublimate solution into the emptied globe, during the performance of the operation, it will help to arrest bleeding 6 Select the needles, slightly curved, for sewing up, and threaded with gut And here, if we please, we may leave the patient, secure in the knowledge that sympathetic disease will not attack the other eye, except under most exceptional circumstances, and that he will possess a movable, though very small, stump on which to adjust an artificial eye, but where a perfect æsthetic result is sought for, and especially in children, for reasons hereafter stated, we advance another stage, and before sewing up the sclera 7 Take the glass sphere best suited to the case, slit the sclera vertically, until the sphere will with difficulty enter the cavity This difficulty only refers to introducing the globe, when it is in, the sclera should unite easily without any tension, and leave no awkward angles, therefore the largest sphere fulfilling these conditions is the best, finally sew up carefully with strong chromicised catgut, taking care to get the scleral edges into apposition Five stitches are generally sufficient Lastly, draw conjunctiva over, and unite at right angle to the scleral wound 8 Spread a thick layer of finely powdered iodoform over the whole conjunctiva, and dress with salicylic-wool in a double layer of Lister's gauze 9 Keep the patient in bed for three days, and dress with hand spray, till all risk of septic trouble has passed over

Should you succeed in keeping the wound aseptic, the reaction is comparatively trivial, if suppuration ensue, the pain and distress may be severe, the orbit becoming infiltrated, and the sclera may slough away I cannot lay too much stress upon perfect asepticity The operation should never be performed without full precautions for its attainment, in any case, it is well to warn the patient that he may have pain in and around the orbit for a week

Union is in most cases rapid A firm round globe results, retaining all the associated movements *ad maximum* and capable of carrying an artificial eye which, when carefully centred and moulded, absolutely defies detection The stump is insensitive to manipulation, so that it seems impossible that irritation can be set up

In selecting eyes for an artificial vitreous body, it is obvious that shrunken globes must be passed over, as also those in which the conjunctiva is in a sloughy condition, as after burns, or destruction of the eye from gonorrhœal ophthalmia, but when the eye is of fair size, and the conjunctiva healthy, however diseased the contents of the globe, and especially in extensive fresh wounds, where primary enucleation is the alternative, the artificial vitreous body can be advantageously used Below is a table comparing the operation with that of enucleation

ENUCLEATION	EVISCERATION AND ARTIFICIAL VITREOUS
1 Complete removal of globe and its contents	1 Retention of the framework of the eye
2 Displacement of all muscular relations and arrest of movement	2 Perfect harmony of muscular movements retained
3 Cicatricial bands are a frequent accompaniment of enucleation The introduction of an artificial eye is thus rendered very difficult, and secondary operations necessitated	3 No bands ever occur after evisceration, unless through burns or other destructive agencies of a similar nature
4 Contractions, specially towards the orbital apex, occur, making new eyes a necessity and preventing all chance of a good fit So, also, the sinking of the glass eye and distortion of the lids is constant	4 A definite size of globe being introduced, no change ever occurs after the parts have quieted down in from six weeks to two months, nor can there be either sinking of eye or distortion of lids
5 The lower sulcus of the conjunctiva being constantly pressed upon by the lower edge of the glass eye—which, indeed, rests upon it—rough granulation, ulcerations, and thickening occur, which necessitate non wearing of the eye for lengthened periods, and may induce sympathetic irritation of the sound eye	5 The grave mischance, mentioned in Enucleation 5, cannot exist with the artificial vitreous body, as the concavity of the artificial eye, being kept closely applied to the convex globe by the lids and atmospheric pressure, is lifted up and rarely touches the inferior sulcus
6 The removal of an eye is a terrible operation to the mind of the patient, more especially as ill fitting glass eyes are so common that there is no solace to be gained from their contemplation, many promising lives having been wrecked through the shrinking from publicity caused by the self consciousness of an ill fitting glass eye	6 An artificial eye which defies detection must exercise an important influence over the mental, bodily, and social status of the wearer
7 Arrested development of the orbit in young children	7 Orbital development is successfully encouraged to continue

There can be no doubt that, if only a portion of these benefits can be conferred, the operation above described should be unhesitatingly adopted To weigh against it, we have 1, an operation requiring care, dexterity, and careful attention to detail, 2 careful dressings, and more personal supervision from the surgeon, 3, a longer convalescence and a longer time before the artificial eye can be used (the artificial eye should be used for two months), 4, it may be urged that we have no guarantee that the success will be permanent, time will show The first case shown at the Ophthalmological Society in March, 1885, has used an artificial eye for eleven months, the result, so far, is perfect A second has used it eight months, I have not seen him since, but know he is well, and others of late date

Let me again point out that, in young children, enucleation is followed by arrested development of the orbit This is an interesting physiological fact, the importance of which cosmetically cannot be overrated It is allowed by most competant observers that the introduction of the artificial vitreous body will encourage the normal growth of the orbit, and assist to maintain symmetry of feature The advantage of the operation is again manifest when I tell you that it may be undertaken at any age from 3 months to 70 years, with equal facility and absence of risk Lastly, I look forward to the placing of the pathology of sympathetic disease upon a basis absolutely incontrovertible through the medium of this operation, for I submit that, should we succeed in preventing secondary inflammatory attacks of the sound eye, we shall have reduced the bacterial origin of sympathetic disease to a demonstration

The correct fitting of an artificial eye being a point of the highest importance, it behooves the surgeon to see for himself and unhesitatingly reject such as do not fit accurately, and the movements of which are not free in every direction, otherwise the irritation caused by the pressure of an opposing edge, will destroy the benefit likely to accrue to the patient from the original operation —*British Medical Journal, Dec 19, 1885*

PARTIAL DISLOCATION OF THE HEAD OF THE RADIUS PECULIAR TO CHILDREN —In THE JOURNAL of January 23, p 94, was given an abstract of a short paper by Mr S H Lindeman, in the *British Medical Journal*, of Dec 5 MR J HUTCHINSON, JR, has a note on the same subject in the *British Medical Journal*, of Jan 2, 1886, in which he says that the best way of regarding this accident is to remember that the orbicular ligament, which in adults strongly grasps the bony head of the radius, in young children has a weaker hold on the same part, which with them is cartilaginous The nucleus for the head of the radius does not appear until the age of 5, and this limits pretty accurately the time up to which the lesion is commonly met with In fact, I could not produce it upon the bodies of children much older than this During traction on the hand, combined supination, as for instance, when the child is dragged along or lifted by the arm, the ligament is very liable to slip up Its attachment to the neck of the radius (only a thin membrane, which I have ventured to name the sub orbicular) may be at the same time torn through, though this probably does not happen in a large proportion of the cases Thus the bone slips a very little downwards, and a very little forwards Mr Lindeman thinks it may reach the depression above the capitellum, this would, of course, be accompanied by marked deformity, which is, on the other hand, conspicuous by its absence If it were not so, the true nature of the accident would not have been so long overlooked, and the lesion ascribed to a displacement of the fibro cartilage at the wrist, etc (see Tillaux's *Anatomie Topographique*, p 549, and also M Goyrand's work) Mr Lucy has observed and kept notes for me of a number of cases at the London Hospital, and we can unhesitatingly affirm that the deformity at the elbow would be overlooked by anyone, even if acquainted with the real nature of the lesion In fact, although a true dislocation, it is rather one of the ligament than of the bone It is perhaps possible, by "strongly supinating and pressing on the head of the radius," to reduce the displacement, but, in my paper, an easier and a surer way is described

Gently flex to a right angle, or a little beyond that, at the same time, gently but fully pronate the forearm By this method, if the case be one of the class described, the ligament will infallibly descend to its right place, again grasping the head of the radius The descent is known by the audible click (Mr Lindeman's "thud" hardly expresses it) which then occurs, and by the relief of the symptoms although the child is sometimes too young to reveal the latter, but the surgeon may feel sure, on hearing the click, that the displacement is reduced Mr Lindeman says that it is very liable to recur, I think this is due to his method (supination and pressure) not always effecting complete reduction We have, with reference to this point, charged the mothers to bring the child back if the symptoms recurred, and in no case have they done so No splint is absolutely necessary, although it is certainly well to keep the part at rest for a time

The reason why pronation and flexion succeed so readily, is probably to be found in the shape of the head of the radius That part of it opposed to the curve of the orbicular ligament, in full supination, has a rectangular edge, whilst in pronation it is rounded off and less deep, hence the ligament easily slips over the latter edge when brought up to it by flexion of the forearm

The frequency of this accident may be judged from the fact that, at the London Hospital, two perfectly typical cases have often been seen on the same day Whereas formerly they were liable to cause doubt and were unsatisfactory to deal with, their nature and the method of reduction are now fully established A few examples may be quoted from Mr Lucy's and my own notes

1 Sarah M , aged 2½, was admitted with left forearm semiprone and motionless, crying with pain on passive movement The mother had pulled the child up by the hand, the forearm being semipronated and fully extended, an hour before On full pronation and flexion a click was felt, and the symptoms disappeared There was certainly no lesion at the wrist

2 John B , aged 2 years, had been dragged from the floor by the hand The child, a fat heavy one, cried, let its arm hang, and couldn't hold anything The forearm was extended and semipronated, full flexion and pronation produced a click, the child ceased crying, and easy movements of the radius followed

3 May F , aged 1 year, was admitted with her forearm bent and semipronated One movement of flexion and pronation caused a click to be heard, and the child actively resisted any further manipulation

4 A young child was diagnosed to have "an injury to the head of the radius," and its arm was bandaged to the side During the next two or three days, she continually complained of pain in the elbow On her second visit, I fully flexed and pronated the forearm, the usual click was heard, and after that the pain and resistance on movement disappeared

Apparatus for Hip Joint Disease —At the meeting of the Medico Chirurgical Society of St Louis, on November 17, 1885, Dr Steele exhibited an apparatus for hip joint disease in the earlier stage and placed a patient upon it to illustrate his method of treatment The apparatus consists of a rectangular frame of flat iron which should be five or six inches longer than the patient, and a trifle wider than the distance from acromion to acromion This is covered with canvas or stout cotton cloth laced tight upon the frame, an opening being left at the centre, corresponding to the nates, for convenience in attending to the wants of the patient Some time ago he exhibited to the Society a portable splint for the treatment of hip-joint disease in the later stages The chief elements in the treatment of these inflammations is rest In hip joint disease we have an inflammation, and the therapeutic agent that would first suggest itself as most natural would be to keep the parts perfectly quiet This is a very simple thing in theory, but there is some practical difficulty in carrying it out This splint is made in such a manner that the patient can be carried about upon it The great objection to most splints is that they allow more or less motion in the joint, and, if the patient is moved about, inflammation may be excited In the earlier stage of hip-joint disease and in the very young it is better to confine the patient on his back by using this splint This apparatus he had presented to another society on a different occasion, but it had never been exhibited in St Louis before The patient lies upon this apparatus and there are shoulder straps which pass over the shoulder and prevent the patient from raising the trunk Perineal straps, attached above to a steel arm springing over from the side of the splint and fastened below to the canvas, afford counter-extension A little steel upright at the foot of the splint affords means of attachment for adhesive straps making extension Two little removable arms or legs can be attached to the apparatus to raise the patient This can be done by the attendant or nurse so that the bed pan can be placed underneath The use of this appliance for two years had given complete satisfaction

At the only hospital in which hip joint disease is exclusively treated—the one in London of Mr Howard Marsh—he confines his patients by straps to the bed He uses adhesive plasters attached to a weight for extension, and elevates the foot of the bed for counter-extension His results are not most promising, Dr Steele thinks because he does not thoroughly immobilize the joint He allows the part to move about more or less After exhibiting the apparatus a little patient was brought in and the mode of application was shown It was shown that by placing him upon this stretcher-splint and making the attachments, he could be carried anywhere The apparatus serves as a stretcher, and at the same time it acts as a splint Both arms, the head, and one lower limb are left free, so that he can play with his toys, and children soon become quite contented Mothers sometimes say it would be better for children to die than to be confined in this way, but they are very well satisfied with this confinement Extension is to be made not only upon the leg, as this may cause trouble in the knee-joint, but upon the entire limb

Dr Prewitt said that he was indebted to Dr Steele for this suggestion, and for something like two years had been using it and had been greatly pleased with the results He thinks it is an admirable apparatus He uses a piece of tubing at the foot and makes an elastic extension which he thinks possesses some advantages One patient from Fort Worth, Texas, started home a day or two after the apparatus was applied, and letters since received speak of the rapidity of the progress of the case and the speedy recovery of the patient He had used this apparatus in every case which had presented itself within the last two years since Dr Steele called his attention to it, in fifteen or twenty, at least —*St Louis Courier of Medicine*, January, 1886

New Method of Removing Foreign Bodies from the Nose —**Dr D Bryson Delavan**, of New York, thus describes his method of removing foreign bodies from the nose "The presence of a foreign body in the nasal cavity is usually attended with marked swelling of the neighboring mucous membrane Its extraction by any of the means in common use is accompanied with pain, often of great severity, and is often followed by copious hæmorrhage The swelling offers, of course, a serious obstacle to the extrusion of a hard body, while one which has increased in size from the imbibition of water becomes all the more firmly impacted Hence, in attempting the removal of the body, more or less laceration of the membrane is likely to occur The pain, with difficulty tolerated by an adult, causes a child to become in almost every instance unmanageable so that an anæsthetic is required The hæmorrhage is usually controllable after the lapse of a few minutes, but may, meanwhile, cause considerable annoyance From our knowledge of the physiological action of cocaine upon the nasal mucous membrane, it is evident that, by its use in these cases, all of the above difficulties may be overcome, for applied to the nose, the mucous membrane becomes strongly retracted, the sensibility to pain lost, and the blood vessels exsanguinated Thus, the calibre of the fossa is greatly widened, the irritation and consequent resistance done away with, hæmorrhage prevented, and the removal of the foreign body thereby greatly facilitated To carry out the method, the occluded nostril should first be cleansed with a spray or a gentle current of some luke-warm alkaline solution, after which a four per cent solution of cocaine should be applied to the mucous membrane When its effect has become complete, the extrusion of the body should be attempted by directing the patient to blow forcibly through the affected nostril Failing in this, it should be drawn out by some suitable instrument Should the patient be too restless to make this practicable, an anæsthetic may still be administered In cases of invasion of the frontal sinus or antrum of Highmore by insects or larvæ, cocaine should be applied to the membrane before the administration of chloroform or ether, in order that the canals leading to these cavities may become as patent as possible, and thus the vapor of the anæsthetic be admitted very thoroughly to the intruder's presence The insensitiveness of the membrane produced by the cocaine will, in these cases, certainly add to the comfort of the sufferer should it be necessary to inject, or still better, to spray the nose with chloroform "—*Medical Record*, Jan 23, 1886

Subcutaneous Cold Abscesses in Scrofulous Children in their Relation to Tuberculosis —**Giesler** has an article on this subject in the *Jahrbuch fur Kinderheilk*, Bd xxiii, Hft 1 and 2 Koch's investigations showed that tubercular disease, wherever located, depended for its cause upon the presence of the spore *bacillus tuberculosis*, this being the evidence, when found, of the tuberculous character of the complaint, and its absence equally showing a non tuberculous character The same disease is likewise producable in animals by inoculation with cultivations of this spore It is also affirmed that all inflammations in which the spore is found, or the products of which cause bacillar tuberculosis in animals, are equally of a tuberculous nature The question naturally arose, then, as to whether the tubercle bacillus was to be found in those diseases which resemble tuberculosis, both clinically and as to their pathological anatomy, especially in the case of scrofula and the results which were obtained varied, some investigators finding tubercle bacilli in all cases, others only occasionally or not at all In lupus the testimony is unequivocal as to its tuberculous character In scrofulous eczema no bacilli have been found in almost all reported cases In the class of cases which is under discussion, namely, subcutaneous cold abscesses in scrofulous children, investigation was first made with the microscope, but after a large number of examinations, with most powerful lenses and very careful search, only a single bacillus was found Seven cases were then selected, and, with material which was obtained from them, inoculation was practiced upon guinea-pigs and puppies, both by subcutaneous and intra-peritoneal application In all cases only negative results were obtained and the conclusion was reached that abscesses of this character, of circumscribed development, and developing from granulation tissue, do not depend upon bacillar tuberculosis, although they may contain giant cells and other lymphoid formations, from which it used to be thought that they were of tuberculous origin They are manifestations of scrofula but not of tuberculosis —*Archives of Pediatrics*, January, 1886

Laceration of the Os and Cervix Uteri, and the Operation of Trachelorrhaphy —The following is the summary of a lecture recently delivered by Dr Graily Hewitt on this subject

The operation is indicated by the presence of considerable hypertrophy of the os the result of laceration and the more so if hypertrophy and eversion be conjoined, by the presence of chronic severe local pain, evidently traceable to the irritation of a raw surface less extensive in amount or traceable to cicatricial hardening at the bottom of the fissure, by the association of marked laceration with a troublesome displacement of the body of the uterus, by the presence of a severe recent laceration, even in cases where no severe symptoms have had time to develop themselves, with the view of preventing (1) cellulitis, (2) the occurrence of cancer, (3) the supervention of symptoms generally, lastly, by the presence of general severe prostration, inability for locomotion, etc., obviously traceable to laceration

The operation itself is not, in most cases, a difficult one, but, in some cases it is so In assisting to hold the cervix down, I have found the large tenaculum hooked forceps, depicted in the last edition of my work on *Diseases of Women*, made by Mayer and Meltzer, of very great utility Some times the nodular hypertrophy renders co aptation of the edges, after paring them not easy, owing to one side of the rent being very short, the other very long Another difficulty is, in some cases, the excessive hardness of the tissues to be perforated by the needle, which is sometimes so great that much force is required to penetrate the tissues The needles need to be very strong for such cases I have found No 6 silver-ware most suitable for sutures, and have generally removed them in not less than ten days Probably it would be better to leave them a week or two longer, in cases where the patient is very weak and nutritive action feeble The importance of a preparatory treatment before proceeding to the operation has already been pointed out.—*British Medical Journal*, January 2 1886

On Thoracocentesis for Empyema —Dr. Paul Blumberg, of Baku, says that at present thoracocentesis is used only for the relief of serous pleuritic effusions to prevent access of air and free incision of, permitting air to enter, is in use for empyema. The author calls attention to the disadvantages of the latter operation (1) The patient is subject to offensive wettings with pus and blood, and therefore exposed to colds and skin-eruptions (2) The possibility of occasioning hæmorrhage by wounding the intercostal artery is a source of anxiety to the surgeon. (3) The operation is of longer duration and of greater painfulness than is necessary

On the other hand, however, paracentesis without admitting the air is not advisable (1) because it would have to be daily repeated (2) because all the pus could not be completely evacuated and (3) because the pus must have continual escape to avoid putrefactive stagnation The author therefore recommends the use of a silver canula one and one-eighth inch in length and of one-sixteenth inch calibre, large enough to admit a double current catheter, and furnished with a plate resembling a tracheotomy canula, this to be introduced with the help of a suitable stylet into the sixth intercostal space and left to remain for three weeks, the cavity being washed out daily with a 2 per cent carbolic solution A rubber tube is attached leading to a basin beside the bed, to carry off the discharge. In fact the author recommends the use of his canula in all cases of effusion, and if they prove serous in character, it may be again extracted He gives two cases —*Deutsch Zeitschr f Chirurg*, October 6 1885 —*Annals of Surgery*, January, 1886

Blotting-paper as an Antiseptic Dressing — Dr Bedoin, in a recent paper on antiseptic dressings suitable for military purposes, said that the requisites were that any dressing to be used on the field of battle must be simple, occupying but small space, inexpensive, and capable of being used for all surgical necessities He believes that he has found a substance which combines in itself all these requisite qualities—blotting or filtering-paper Before being used for surgical purposes, it should be disinfected by a lengthened exposure to a heat of 120° Cent., and by immersion in an antiseptic solution, and afterwards dried Wounds are dressed by the application of seven or eight layers of this paper, the whole being covered with gutta-percha tissue, and a bandage applied The dressing weighs only about 40 grammes, so that each soldier can carry one In the ambulance, this dressing can be applied by the surgeon with any others that it is thought well to employ —*British Medical Journal*, January 2 1886

Iodoform in Uterine Catarrh —Kugelmann, having noticed that iodoform very promptly cures coryza and laryngitis concluded that it would be beneficial in cases of uterine catarrh. He introduced the powder into the uterus by means of a very fine catheter The applications were renewed twice a week, and with excellent results The catarrhal hypersecretion diminished or ceased immediately in every case —*Gazette Med de Paris* No 52 1885

ELEMENTS OF PROGNOSIS IN BRIGHT'S DISEASE

In the issue of THE JOURNAL of January 9 we published a very interesting article on this subject by PROFESSOR AUSTIN FLINT, of New York The paper is both valuable and timely, although far from being exhaustive It was prepared for the purpose of "leading" a discussion of this important subject before the New York County Medical Association, and its author was obliged to compress his paper to the limits allowed by the time and place But Prof Flint presents some excellent thoughts in this brief paper, which ought to be urged upon the profession both frequently and persistently We propose to indicate and comment upon some of the more important points presented

Prof Flint first mentions the popular belief that chronic Bright's disease is always incurable, and to the fact that this belief "reflects the views of the medical profession"—and he adds, "this view of the prognosis is not far from the truth" With this most discouraging view we cannot agree, and we regret that it should emanate from so high a source It is indeed unfortunately true that the great majority of the cases of chronic Bright's disease—or, as Grainger Stewart so aptly puts it, "Bright's *diseases*"—end fatally, but this fact does not prove that it need be or ought to be so It is not creditable to our profession that every case of chronic Bright's disease is abandoned as hopelessly incurable Such is not the case A fair proportion of the cases of chronic parenchymatous nephritis are certainly amenable to treatment and to cure Nor is chronic interstitial nephritis by any means necessarily a fatal disease The great difficulty about it is simply this,—a diagnosis is not reached until the kidneys are hopelessly damaged And herein lies a grave charge of remissness against a large majority of us, patients are constantly treated for "dyspepsia," "biliousness," "headache," "spinal irritation," and a dozen other imaginary evils, when boiling a little of the patient's urine would clear up all doubts, and light the way to rational treatment We are not making an exaggerated statement when we say that fifty per cent of the victims of Bright's disease are in a greater degree the victims of a tardy diagnosis And the very fact that this disease steals upon us like a thief in the night, almost without appreciable symptoms, ought to double our efforts to detect its very incipiency. When the test-tube is used as commonly as the stethoscope, deaths from chronic nephritis will steadily diminish But when a physician firmly believes that a disease is incurable, he is not likely to put forth any very brilliant efforts in attempting to cure it. And when our most prominent teachers pronounce a disease incurable, the doctrine is in danger of becoming "popular"

Prof Flint mentions the well-known difficulty of determining whether a given case of acute nephritis is really acute primarily, or an acute explosion occurring in course of a chronic case And this leads us to make an assertion which will doubtless call forth a most hearty dissent from at least nine-tenths of the profession, namely that there are, comparatively. very few cases of primary idiopathic acute nephritis, but that the apparently acute cases, except the scarlatinal form, are preceded by a chronic lesion, possibly very slight indeed, but nevertheless real and appreciable This conclusion is based upon facts and arguments which we cannot state within our present limits, but it is our purpose to present this branch of the subject upon a future occasion

In the paper under consideration Prof Flint does a real service to pathology and therapeutics, as well as to prognostics, in broadly recognizing "sub-acute nephritis" as an idiopathic form of disease, and, as he well says, these cases "have not received sufficient attention by medical writers" Of late years, it has become quite too much the fashion to drop sub acute inflammations out of our calculations altogether An inflammation is either acute or chronic, and there is no halfway work about it according to our present incisive pathology Yet it is a clinical fact, that cases are constantly occurring, of renal and other inflammations, which occupy a middle ground and are truly sub-acute And this fact is a most important one in its relations to prognosis and therapeutics "Sub acute" has a much more encouraging and hopeful sound, from a therapeutic standpoint, than "chronic" He schedules, it will be remembered, the "elements of prognosis" in cases of chronic Bright's disease as follows

"*First* the kidneys must not be damaged beyond a certain extent," and inasmuch as one kidney is capable of performing the renal function, "it follows that a lesion may have impaired the functional power of the organ at least one-half, without necessarily giving rise to important symptoms of disease *Second* the important organs of the body other than the kidneys must be capable of performing satisfactorily their respective functions" *Third* "the laws of health, relating to alimentation, exercise, exposure to cold, mental excitement and habits of life must be observed" "Now," he continues, "suppose these, as we will call them, accessory conditions to be fulfilled, and a lesion of the kidneys to exist which diminishes their functional ability one half, *and the disease not to be progressive*, life and health are compatible with the existence of chronic Bright's disease for an indefinite period" To this we must agree In fact, a patient combining in his own person all these remarkable conditions would make a pretty fair life insurance risk, and his heirs would wait wearily for the reading of his will

But how many of us have seen a case of Bright's disease presenting all these conditions? Have we ever seen a case of chronic nephritis in which the 'important organs of the body other than the kidney" were "capable of performing their functions satisfactorily' (?) Is it not a fact that their functions are necessarily, invariably and unavoidably disturbed by the vicarious labor they are called upon to perform? Every candid clinician of experience must answer this question in the affirmative In truth, every case of chronic nephritis, of whatever type, involves not only functional but also lesional changes of other important organs Dr Flint speaks of non-progressive or latent Bright's disease, as though latency or inactivity might be safely predicated of a certain number of cases, as an element of prognosis There are cases of Bright's disease which progress very slowly, but they are few and far between, there are other cases which exist for an indefinite and unknown period of time before they are discovered, there are cases in which the urine is non albuminous at times and even for considerable periods, and there are cases from which the albumin slowly disappears never to return, but in all these types there is *progress, constant* and unceasing, and we cannot very well understand the term "latent" as applied to a process of disease, or to a process of recovery Progress may be so slow, in either direction, that a green old age may be reached before death or recovery takes place, but there is progress, activity and movement, nevertheless

In this connection it may be added that, in our opinion, the author entirely omits one important factor in the prognosis of Bright's disease, namely careful inquiry into the type or pathological variety, whether parenchymatous (or, as Dickinson prefers, tubal), interstitial or amyloid, for until the physician has sharply defined ideas as to the intrinsic pathology of a given case, he is in a poor condition to prognosticate concerning it

The remainder of the paper in question seems to be beyond criticism Especially are to be commended his remarks as to the question of "renal adequacy," and how it is to be ascertained Practitioners rarely fail to inquire as to the presence of albumin and casts, but too often neglect entirely the question as to the eliminating power of the kidneys As Dr Flint well says, "albumin and casts in the urine show that the kidneys are doing what healthy organs ought not to do, but the more important inquiry is, are they doing what healthy organs ought to do?" And this, as he further insists, can be ascertained by simply measuring the diurnal quantity of urine, and taking its specific gravity So long as the quantity of urine passed and its specific gravity give assurance that a sufficient degree of elimination is going on, "the indication for diuretics, hydragogues and sudorifics is entirely wanting We may add an emphatic approval of the protest against the indiscriminate use of diuretics, hydragogues and sudorifics, when they are not only not indicated but must do positive harm We have long and imperatively insisted upon this very point, and are glad to have the support of so high an authority as Dr Flint Especially, must we object to the needless and generally harmful use of diuretics in chronic nephritis, or, in fact, any lesion of the renal organs Dire necessity may compel the use of diuretics, but it must be regarded as an unfortunate necessity, since the prime condition of recovery in case of a diseased kidney is physiological rest, and diuretics do not tend to this

On the whole then, we must commend the thoughtful paper of the distinguished clinician to the careful attention of our readers Every such paper becomes a permanent and important integer in medical science, and we can only regret that in this case it was restricted in length

INTERMITTENT FEVER AND ENDOCARDITIS

The intermittent fever of malarial origin is so common an occurrence that even the humblest practitioner considers himself capable of its recognition. Indeed, so confident is he of his unerring ability in this direction, that he readily falls into the habit of branding nearly every fever, when accompanied by chilliness, as malarial. This habit is not only convenient to himself, by saving trouble and hiding ignorance, but it is also highly satisfactory to both patient and friends, since it agrees with their preconceived opinions. There are intermittent fevers, however, that are of very different origin. Their type is irregular and their course is particularly stubborn to treatment. It is probable that in most cases they conceal the original disease beyond detection.

Such a fever is that due to endocarditis. It is of great clinical interest, since a clearer knowledge of its peculiar features may aid in the recognition of that notoriously obscure affection. In 1882 Leyden contributed an excellent paper on this subject to the *Zeitschrift für Klinische Medicin*, which may be found in vol. 4 of that journal. He says the subject merits greater study than it has received. References to it in medical literature are scanty and for the most part are confined to observations upon the rigors characterizing most attacks of endocarditis. The older writers speak of the fever of this affection in only general terms. Even Traube's writings mention it but twice. In the second part of his work, while commenting upon a case of pyelophlebitis, he remarks incidentally that the fever of endocarditis is also intermittent. In the third part of the same work, Fraenkel, in a report of three cases of endocarditis, emphasizes the diagnostic value of rigors in this affection. Rosenstein, in Ziemssen's work upon special pathology and therapeutics, divides endocarditis into two classes according to the character of the fever. In one it is typhoid in character, and the differential diagnosis is often difficult. In the other the fever is pyæmic, being characterized by the formation of metastatic abscesses and by rigors. Litten likewise distinguishes a septic variety of the disease, in which the fever is more intense and irregular than in rheumatic endocarditis. Abscesses occur in numerous parts, accompanied by rigors. Such then, according to Leyden, is the desirability of a more detailed account of this form of fever, that he divides it into four groups or varieties.

In the first group the endocarditis attends and constitutes an essential feature of blood poisoning, whether from puerperal septicæmia or pyæmia resulting from traumatism or operations. This form of endocarditis is also observed in connection with phlebitis and abscesses, as shown by a case of hepatic abscess reported by Leyden. In his second group the endocarditis is manifested by a fever of greater or less intensity and irregularity. Rigors are present but conform to no established type. The cases reported by Traube, as well as several of Litten's, belong to this group. *In the third and fourth groups the course* of the fever closely resembles an ordinary intermittent, yet for the most part is irregular. At other times the paroxysms come and go for a while with the periodicity of a quotidian or tertian fever. In the third group, moreover, the endocarditis is not discoverable, and its existence is only surmised, or it is recognized only towards the close of the fever. The fourth group, on the contrary, is discovered with comparative facility and is therefore the most interesting. Here the endocarditis attacks an already diseased heart, although the disease may have been so fully compensated as not to have given rise to symptoms.

In the third group, owing to the absence of all functional disturbance or physical signs of cardiac disease, other than can be reasonably attributed to the fever, the existence of endocarditis can only be inferred. *It is rendered certain only by the subsequent* development of a valuable lesion or by the autopsy. The real nature of the fever is obscure. Since there is always enlargement of the spleen it may be an abnormal and stubborn attack of malaria, and incipient tuberculosis, or there may be a deep seated abscess or a pyelophlebitis of a cerebral sinus, or of the portal vein. Whatever it may be, it resists all ordinary remedies, such as quinine and salicylic acid. The patient becomes anæmic, wastes away and at length succumbs to the disease. In the fourth class of cases a simple endocarditis has existed previously, leaving a fully compensated valvular lesion behind. Some deleterious influence now lights up a fresh inflammation which this time is malignant. The exact nature of the toxic agent cannot be determined perhaps, but Leyden thinks the fibrinous vegetations already existing upon the endocardium furnish favorable nidus for attachment and development of micro-organisms. Affected valves may become healed by the adhesion or sclerosis of their surfaces, but ulcerated areas are prevented from healing by the layer of infected material covering them. The organism cannot get rid of these parasitic bodies which continue to thrive at the expense of the patient's system. Yet not alone the general health suffers, the heart muscle becomes invaded by areas of myocarditis which tells upon the vigor of the left ventricle.

As illustrating this last form of the disease, Leyden narrates the history of four cases, two of which came to autopsy. In one, the attack seemed to result from residence in a damp house. Another began to feel ill after having eaten oysters that were not quite fresh. In the third the disease could be traced to gonorrhœal rheumatism, while the fourth appeared to be due to malarial poison. All were subjects of previous heart-disease.

PROGRESS OF THE OPPOSITION TO THE ORGANIZATION OF THE INTERNATIONAL CONGRESS—SIGNS OF THE END.

When the American Medical Association at its meeting in New Orleans simply exercised its right to enlarge its Committee on the Organization of the Congress, and make it more truly representative of the whole profession, a few leading men having the control of two or three prominent medical journals captiously denied the right of the Association to meddle with the matter. They were soon compelled to abandon that position as untenable.

They next made a sudden and concerted attempt to prevent the Enlarged Committee from making any progress in the work of organization by the most reckless efforts to keep members of the profession from accepting any official positions in the Preliminary Organization of the Congress. They denounced the action of the Association, and openly avowed their preference to have the whole profession of the country disgraced by a withdrawal of the Congress to some other country rather than to make any honorable and fair concessions to the fairly expressed wishes of the National Association. In the meantime, the properly Enlarged Committee on Organization quietly progressed with their work, adopting complete and satisfactory rules of organization, and appointing the provisional officers of the Congress and of the Sections, thereby providing an efficient Executive Committee of the Congress to take all further control of its affairs. The Executive Committee promptly commenced its work by publishing the Rules and plan of organization for the Congress both in this country and in Europe. The announcement has been received with favor on both sides of the Atlantic, and active progress in the preparation of programmes of work for the several Sections is being made. Time has thus demonstrated that every effort of those who had banded together in opposition to the work of the legitimate organization had actually failed.

The Executive Committee, desirous of removing all excuse for continued divisions, and disregarding all personal feelings, honorably tendered as many appointments in their own body as the Rules of the organization permitted, to the most eminent of those thus far in opposition. Instead of meeting a prompt acceptance, the appointments were submitted to the organized caucus of the opposition in Philadelphia, in which were made professions of extraordinary regard for the National Code of Ethics and for the welfare of the National Association; but it ended in suggestions of an utterly impracticable character. More recently, as shown by our special Philadelphia correspondent, in THE JOURNAL of January 16, they assumed still further the rôle of professional harmonizers and special friends of the American Medical Association, while electing delegates to the Association in the meeting of the Philadelphia County Medical Society by methods unknown to the usages of the Society. This is a practical acknowledgment of the right and duty of the Association to make good all arrangements implied by the invitation to the Congress given in behalf of the profession of the United States.

The sample of their work done in the Philadelphia County Medical Society shows their last card, which consists in a desperate effort to control the election of delegates to the meeting of the American Medical Association in St. Louis, in May next. Their methods and purposes are now fully apparent to the profession at large, and their last game, under professions of harmony, will avail them no better than their former one of bluff.

"MUTUAL PROTECTION AGAINST BLACKMAIL."

The increase in the numbers of the legal profession does not seem to have done much towards disproving the old saying that "The end of the laws is to defeat Justice," and it is entirely probable that the saying will remain true until the intelligent American juror is legislated out of existence, and with him his counterpart, the "shyster" lawyer. In the preceding pages of this week's issue of THE JOURNAL is to be found a timely article on "Mutual Protection against Blackmail," by DR. EDMUND J. DOERING, of Chicago. We need not repeat the many and forcible arguments made in favor of a "Protective Association," as they have been well stated by Dr. Doering and the correspondents whose letters are quoted. We will therefore confine our comments to the objections which have been made against such an Association.

The first objection brought forward is, that the fact that a physician is a member of a protective association may prejudice the jury against him As a matter of fact Dr Doering quotes two legal opinions to the effect that the fact of membership in an association of this kind could not be, as a matter of law, properly brought before a jury, and that "the fact that the defendant was a member of such a society would not be competent evidence" If, however, the fact should get into the case in any way, it could be equally brought out that the association was not for the purpose of paying judgments, but only to defray legal expenses In this connection may be mentioned the suggestion of Mr O H Horton, that in specifying the objects of the association, they should include the protection of the public as well as of the physicians But Mr Horton's suggestion that the association should promise to keep professional secrets out of the courts is unwise, we think, as being a little in advance of common law, which does not recognize the right of a physician to withhold any secret

A second objection is that the counsel employed by the association might not be the man whom a few individual members would select to conduct their own case This is no objection at all to the formation of an association Travelers may as well object to riding on certain railway lines because the family physicians are not the surgeons to that road The association could not and would not undertake to compel the defendants to employ its attorney, it is simply for the purpose of assisting any member who may be so unfortunate as to be blackmailed, and see that he gets as much justice as can be had at the hands of a jury Many physicians cannot afford to employ counsel, and run the risk of having heavy damages awarded the prosecutor A judgment of two or three thousand dollars would be financial ruin to some physicians—for there are still some who are not capitalists As regards the manner in which some of these suits are said to be brought, we may say that it is *illegal* for a lawyer to undertake a suit on shares, or for what he can make out of it But the real difficulty in a great number of the malpractice suits brought is that the lawyers are not posted on the case Very many lawyers seem to think that the subject of fractures can be learned in a week, they do not know medicine, and know but very little legal medicine as a rule Should such an association be formed, then, the first duty will be to get an attorney who knows enough of medicine to undertake a case without being coached and "crammed" by the defendants If organized and conducted on proper principles, there seems to be no good reason why such an association should not be productive of good

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, January 18th, 1886

D W GRAHAM, M D, TEMPORARY CHAIRMAN

DR E J DOERING read a paper entitled

MUTUAL PROTECTION AGAINST BLACKMAIL

(See page 114)

DR F C HOTZ said that the extract of his letter to Dr Doering, which was incorporated in the paper, indicated that at the time it was written he did not think favorably of the project And, after listening with much interest to the doctor's arguments, he saw no reason for changing his opinion Professional reputation and honor is the most personal of all personal property, if he lost it, it does not hurt anybody but himself, and therefore if any attack be made on it he should certainly wish to employ among the able lawyers the one in whose ability he had the greatest confidence But he was not sure whether the lawyer retained by this protective union would be the one to whom he should like to trust the defense of his reputation The attorney might be as able, or abler, than the lawyer of his own choice, but should the case go against him, he should never feel satisfied that the lawyer had done all that could be done for him unless he had full confidence in him It is with the lawyer as with the physician, a question of confidence, and his patrons find no fault with his treatment as long as they have implicit faith in his ability

An objection of greater weight, however, has been urged by several of the doctor's correspondents in asking what possible effect it might have if the fact was brought out in court that the defendant belonged to such a union? The lawyers whose opinions were obtained and read by the doctor say it cannot legally affect the case There is no doubt but what this is true But the verdict of a jury in malpractice suits is not determined by the legal aspect of the case, and circumstances which cannot have any legal effect upon the case have often made a deep impression upon a jury and decided the case against the physician To illustrate In Dr Bettman's first trial the experts of the prosecution testified so unreservedly in the doctor's favor that had the case been then submitted to the jury without arguments, the doctor would have been acquitted at once To fortify his cause Dr Bettman's lawyer called a number of experts whose testimony was of course only cumulative Now what did the prosecuting lawyer do? Did he make an effort to break down the expert evidence by scientific arguments? No, sir, but he wiped out its effect upon the jury by the mere waving of his hand, speaking thus "The defense has piled up a mountain of expert evidence But, gentlemen of the jury, what does it all amount to? These doctors are working together in the same hospital Don't you see that they have a common interest to sustain each other, because every one of them may be in the same fix some day? Don't you know they are clannish? They won't admit that one of them can make a mistake. O, no!" One could fairly see the impression this harangue made upon the jury, and they rendered a verdict against the doctor, though it is certain the lawyers will say the fact of his being associated with the experts in the same hospital should and could legally not prejudice the jury. But it evidently did all the same. And after such experience, can you for one moment believe it would not damage the physician's cause if it was shown he and his experts belonged to a society formed for the express purpose of mutual assistance in malpractice suits. A mighty poor lawyer indeed he would be who could not make a great deal out of it before a jury.

Very interesting was that part of the paper in which the doctor evolved his idea how this new society could prevent, ward off, malpractice suits. He believes the shysters would not be so eager to engage in this business if they knew they had to fight a corporation with plenty of means to employ the best legal talent. Why this should discourage those fellows, it is hard to understand. They do not sue poverty stricken doctors. Whom they select for their victims they suppose to be rich and consequently able to employ a good lawyer. They do not expect to have an easy game, but why should they not try it? They don't risk anything by it. The blackmailer's stake is only two dollars and a half for filing his application, and his lawyer's stake is his time, which is not worth much anyhow. So you see, they have nothing to lose, but much to gain. What difference should it make to them whether the opposing counsel is engaged by one physician or by one hundred? If you wish to devise means by which this blackmailing nuisance can be stopped, or at least reduced to a minimum, you must try to get to the roots of the evil, that is, you must find the causes which usually bring it forth. And you will not go far to find them, for you find them right at your door, in our own profession, in the shape of *indiscriminate dispensation of gratuitous services and of unkind remarks of one physician about another*. Physicians are altogether too quick to give their services gratis to almost anybody at any time. But you know very well people do not value very much what they can get for the mere asking, they do not think much of what they get for nothing. And it is also a widespread notion (especially among the lower uneducated people) that the quality of service is regulated by the amount of money they pay for it, that the treatment at a free Dispensary, because gratuitous, is not the same, not as good as at the physician's office where they have to pay for it. These people cannot persuade themselves that a physician will take the same interest in a case whether or not he is paid for his services. The poor, therefore, are always suspicious that they do not get their full share of attention, they are quickly ready to charge their physician with carelessness if the case goes wrong. And with a patient in this frame of mind it takes but very little encouragement to begin a suit for damages. And in nine out of ten cases, doubtless, this encouragement is furnished by the members of our own profession. He did not mean to charge physicians with purposely, wilfully instigating a lawsuit against a professional brother. Though this has been done, such extraordinary baseness is a rare exception.

What Dr. Hotz had reference to is the inconsiderate, careless, thoughtless habit of expressing an opinion about a case, or a colleague. To illustrate: A physician at a Dispensary shows a bad case to professional friends, and without thinking of the possible evil consequences, makes in the presence of the patient some remark like this: "Well, perhaps I ought to have done this or that." The patient, already laboring under the impression that he was not fairly treated because he could not pay, sees in the doctor's remark the strongest confirmation of his suspicion, goes to a shyster and begins a suit for damages. And doubtless, in a similar way the mind of a patient is often poisoned and set against his physician by a careless or unkind remark of another physician. So many physicians are always ready to express their opinion about their colleagues in the presence of anybody, or to criticise their professional acts upon the information received from a patient or some old woman. Now you all know how these people misconstrue the words of a doctor, how they pervert the facts inadvertently. You must admit you cannot rely on what patients tell you, and you cannot form an opinion that is worth anything of a case you have not seen or been informed about by the attending physician. Why, then, don't you say so when some busybody asks you what you think about that case of Dr. H.? Or if you know the physician, say he is competent to attend to his own business, if you don't know him, change the subject. But at all events, unless he be a notorious quack, refrain from uttering any words which even only insinuate the possibility of a mistake or want of skill of your colleague.

Stop running each other down, stand by each other, sustain each other, "stick together and be clannish," let it be understood in public that no reputable physician will prostitute himself by going to court as expert for a blackmailer. If all the reputable physicians of this city adopt and act on this principle, blackmailing the medical profession would soon be a thing of the past, and malpractice suits more effectually prevented than by the organization of a protective union.

Dr. P. S. Hayes said that from his costly experience in a malpractice suit he felt that an association such as suggested by Dr. Doering would be of great service. The lawyer employed by such an association would speedily acquire such a fund of medical knowledge that he would be considered an expert in malpractice cases. He would not require an amount of coaching necessary to prepare for any given case as would be requisite in the case of a lawyer who had had no experience in such cases. His opportunity for obtaining information in a given case would be largely extended, for each member of the association to whom he might apply would be interested in giving him the desired knowledge. He would soon become acquainted with medical witnesses and know which would give the best testimony in any case.

An association of the character suggested by the paper, might be a means of educating its members in regard to laws bearing on the rights of physicians and their patients, now not generally understood. For one he is heartily in favor of such an association, and should give it his hearty support.

Dr. G. C. Paoli said Dr. Doering's paper is not only a valuable one, but contains such a high, noble, charitable feeling, that the Society ought to be grateful to him. He wondered that such steps had not been taken before, because so many of our professional brethren have not only suffered annoyance, but pecuniary loss as well. How can we expect from an ignorant jury a decision based on scientific knowledge and justice?

Dr. F. M. Weller said that the subject of the paper was worthy of consideration; that the discussion of the formation of an association with an object so widely different from the Medical Society seemed out of place; the one essentially scientific, the other in the nature of an insurance. The right to form such an organization was unquestioned; the policy should be considered by each individual. That while any one might be made the object of blackmail, he believed that charges of malpractice more frequently arose from the ignorance of physicians of the statutes affecting the practice of medicine, especially those of the criminal code, and of the rulings of the courts in cases.

Dr. H. D. Valin read a paper on

THE ORIGIN AND SIGNIFICANCE OF THE SEXES AND THE DETERMINATION OF SEX IN UTERO.

He said that it is not generally known that intermediate steps exist by which sexual generation is evolved from a primitive mode of conjugation of two or more similar organisms. The process of conjugation observed in the slime moulds resembles a sexual process of extreme simplicity. But this union seems to take place between undifferentiated individuals, and as no sexual organ or secretion is present, it could not be called sexual, and it is only a step higher than that observed by Ch. Robin in the noctiluca, individuals of which sometimes swallow others of their own species as they would a particle of food.

The evolution of the sexes is epitomized in the three following species of the volvox family: *Pandorina morum*, *Volvox globator*, and *Volvox aureus*. In the first the spermatozoids are not differentiated from the granules of the ovum, in the second they are so differentiated, and in the third the two sexes exist each in a different colony.

In the animal kingdom, some species of mollusks contain an organ (ovo testis) from which spermatozoids as well as ova are produced. In many animal species both sexes are contained in one individual, as in the case of tape worm, leeches, earth-worms, barnacles, oysters, some star fishes; and among the vertebrates such is the case in several species of serranus, as well as in other fishes. However, most of the vertebrated animals have the sexual organs distinct in two different individuals, but a condition closely resembling hermaphroditism often occurs by reversion as an anomaly; and should any one disbelieve that some remote progenitor of the whole vertebrate kingdom has been hermaphrodite, there remains the facts "that at a very early embryonic period both sexes possess true male and female glands" (Darwin), and in each mature individual rudiments of some of the sexual organs of the opposite sex are extant.

The condition of hermaphrodite is advantageous enough as long as the struggle for existence is but slightly marked, but in higher life, where the least advantage is of moment, hermaphroditism gives rise to separate sexes in the following manner: those hermaphrodites whose spermatozoids and ova mingle with the generative products of other hermaphrodites breed a progeny which is more vigorous than that resulting from a single hermaphrodite, and thus copulation between hermaphrodites became established is the struggle for existence; but this is an observed fact, for Darwin said: "There is reason to believe that with all hermaphrodites two individuals, either occasionally or habitually, concur for the reproduction of their kind."

Of course that set of organs in one individual hermaphrodite which had been used more frequently would the better perform their function, while the opposite set would become less active; and then we would find some hermaphrodites with better developed male organs, and others with better developed female organs; and the progeny resulting from the union of two such more differentiated individuals would be especially favored in their struggle for life and would breed individuals in which one set of organs would be abortive, while the other would be highly developed, as is the case in as high an animal as man. Such a transitory stage as alluded to above is met in mollusks, and in the common oyster; the genital cœca in any given individual are found to be either almost all ovigerous or almost all spermigerous (Huxley).

In the case of hermaphroditic human beings the organs of one sex almost always predominate over those of the other.

The foregoing facts and inferences warrant me in formulating the following hypothesis, which will explain the law of heredity. In hermaphrodites, while the organs of one sex become more highly evolved, at the expense, as it were, of the opposite sex's organs, this latter set, as embryology proves, is slow to disappear, and concentrates itself in the germinal matter. In other words, as the male organs become better developed, the spermatozoids acquire a faculty for developing a female offspring, and vice versa. This hypothesis is based chiefly on the facts that the queen bee (Huxley) contains a male germ in each of her unimpregnated ova, while the male bee transforms, by means of his spermatozoids, the same ova into females.

Determination of Sex in Utero.—In case each sex generally reproduces the opposite, as I claim, it is easy to understand why the number of each remains about stationary under ordinary circumstances. The law of Thury, of Switzerland, that "conception following menstruation produces females, and conception preceding menstruation produces males, harmonizes with my hypothesis if we consider that a greater number of spermatozoids and more active ova will reach the ovum in the uterus than would in the Fallopian tubes and in the ovaries, and should any given cause act to reduce one sex, the other sex would thrive the better and would reproduce a majority of the rarer sex, thus restoring the equilibrium, and insuring an equal number of either sex in the progeny.

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, January 7th, 1886.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

W. H. H. GITHENS, M.D., SECRETARY.

DR. HOWARD A. KELLY exhibited recent specimens of

PYO-SALPINX, HYDRO-SALPINX AND PAPILLOMA OF THE HILUM AND GELATINOID THICKENING OF THE FALLOPIAN TUBE.

The histories of the cases will be given at some future time.

DR. WILLIAM GOODELL stated that while he recognized the necessity for operation in pyo-salpinx, he does not think it necessary in hydro-salpinx. He now refuses to operate in some cases of cystic disease in which one ovary may contain a cyst as large as an orange, or in which the tube may be distended to the size of a sausage, because the sufferings of the patient and her general symptoms are not severe enough to warrant the operation. In many of these cases the symptoms may all be removed by the rest treatment, and it should first be tried. Small cysts are frequently found in ovaries, especially when uterine fibroids are present, but they do not necessarily develop into large ones. In many cases the cause of pelvic symptoms can be diagnosticated by exclusion only, and even when small cysts or dilated tubes can be felt, treatment should be first tried, and will be sometimes successful without operation. He thinks the error of the present time is in the direction of too much surgical interference.

DR. E. E. MONTGOMERY remarked that there was a class of cases suffering from small ovarian cysts or distended tubes in which the rest treatment or any other loss of time could not be thought of, and in which operation seemed imperative. This was on account of the pecuniary condition of the patient, who may be self-supporting or who may be the only support of others; the suffering and exhaustion of the disease incapacitate them from work; relief is imperatively demanded, and he considered operation justified.

DR. GOODELL recognized this element of poverty, and has operated for this reason in some instances. He was led to make his remarks by a case now under his care. A lady was sent to him for operation after an opinion had been given by an experienced gynecologist of another city that relief could be obtained by operation only. On one side the ovary was enlarged, and the other ovary was prolapsed and tender. Rest treatment had wholly cured her. In these remarks he did not mean to cast reflection on any of Dr. Kelly's cases. Pus was present in all of them, and operation seemed to be demanded in all.

DR. B. F. BAER has been strongly impressed lately with the views expressed this evening by Dr. Goodell. Dr. Baer thought all conservative means should be tried before operating.

DR. KELLY replied that he had presented the specimens purely from an anatomical and pathological standpoint, and that he will give the histories at some future time, when the results of operation are well demonstrated. In each of them operation was imperatively demanded to save life. It is in such cases as those presented this evening that the great work in the future must largely lie. If the details of ovariotomy have been perfected in such cases as these the chapter is only being opened. They are not examples of Battey's operation, or Tait's operation, but stand as representatives of classes of disease well defined with equally well defined indications for treatment. The extraordinary difficulty of digging such masses as these out of the pelvis makes operative interference very fatal, although it is the only resort.

DR. WM. GOODELL read a paper entitled

A YEAR'S WORK IN LAPAROTOMY.

During the past year he had had forty-four cases of laparotomy, with four deaths, as follows:

	Cases	Deaths	Recovery
Ovariotomy	28	2	26
Oophorectomy	9	1	8
Hysterectomy	2	1	1
Exploratory incision	4		4
Pelvic abscess	1		1
Totals	44	4	40

Of these forty-four cases, twenty-five had been operated on at his private hospital, with two deaths; twelve were operated on at the Hospital of the University of Pennsylvania, with one death; and seven were operated on at the homes of the patients, with one death. Of these four deaths, one only was due to septicæmia, and that a case of oophorectomy, occurred in a private room of the Hospital of the University. It was not, however, due to hospitalism, but to the adverse circumstances of the case. The ovary and oviduct were filled with pus, and so matted by inflammation to adjacent structures that only a portion of them could be removed, and that in fragments. The pus unavoidably escaped into the peritoneal cavity, which was carefully cleansed and a drainage tube put in, yet a fatal inflammation set in. Another death was due to shock after removal of the womb containing a fibroid tumor with extensive adhesions, and weighing seventeen pounds. The two deaths after ovariotomy were not due to septicæmia, and are somewhat mysterious. One case was operated on at the patient's home in Bedford, Pa., and Dr. Goodell did not see her again. The cyst was parovarian, weighing forty-three pounds, was without an adhesion and was easily removed. The stitches in due time were removed, the bowels were opened and everything did well for twelve days Then obstinate vomiting set in and the lady died on the seventeenth day Six months previously she had had an analagous attack of obstinate vomiting in which her life was despaired of The fourth death took place from a supposed attack of malaria to which the patient was liable Both ovaries had been removed, the larger one weighing about thirty pounds There were omental adhesions and very firm parietal ones, needing a number of ligatures She recovered promptly from the operation, the wound united, the stitches were removed, and she was allowed to sit up out of bed On the seventeenth day malarial fever with bilious vomiting set it, and she died rather suddenly on the twenty-first day, with symptoms of heart-clot

Of the nine oophorectomies, four were performed for ovaralgia, three for bleeding fibroid, one for epilepsy, and one for a menorrhagia which had resisted every known therapeutic measure In three cases of ovariotomy, all of them with papillary cysts, rupture had taken place a few hours before the operation, but although the peritoneum seemed thickened and injected, no bad result followed He considered papillary cyst to be benign in the very great majority of cases, and that the danger from the escape of the ovarian fluid into the abdominal cavity was very much overrated He had not refused to operate in a single instance of ovarian tumor, no matter how low the patient was or how firm were the adhesions He had consequently had several exceedingly difficult operations Out of his twenty-eight ovariotomies there were twenty one with adhesions In four the adhesions were universal, in eight more they were intestinal, and in three they were uterine This very large proportion of adhesions, when compared with those of European operations, he could explain only on the theory that physicians in this country have not been educated up to the idea of an early operation, and to a recognition of the evils of tapping In the successful case of hysterectomy a tumor weighing eight pounds was removed, together with a portion of the enlarged womb As the uterine cavity was not involved, the large pedicle was transfixed, tied and dropped The four exploratory incisions were made with a view of removing the ovaries on account of fibroid tumors of the womb But in each the tumor was so fixed by adhesions that the ovaries could not be reached, and the patients had previously stipulated that in that case the uterine growth was not to be removed All did well So also did a case of pelvic abscess communicating with the bladder and rectum It was opened *per vaginam* by means of the abdominal incision, by which its exact position and size were determined

With regard to the technique of the operation for laparotomy, Dr Goodell stated that he used the ordinary knot and Staffordshire knot indifferently, that he now in the long incision cuts directly through the umbilicus instead of going around it on the left side, that he includes the recti muscles and all the tissues in the abdominal sutures, and that while not a very firm believer in the spray part of antiseptic surgery, he had resorted to the atomizer in every case but one, and that one did as well without it as most do with it

Dr Montgomery thought Dr Goodell should be congratulated upon his success, which is remarkable for operations in unselected cases in the United States He thinks the knowledge of the safety attending the application of Monsel's solution to oozing abdominal surfaces very gratifying He would have used it recently but for the fear of bad after effects He must, however, again enter his plea for the second ovary In young women small ovarian cysts are common, they are frequently found in post mortem examinations where there had not been the slightest evidence during life of their presence, and evidently these small cysts do not necessarily develop into large ones The two cases of secondary ovariotomy reported by Dr Goodell are not sufficient to warrant the rule of removing the second ovary when it is but slightly diseased As a counter-weight to Dr Goodell's cases he would mention that in the instance of a young married woman from whom he removed an ovarian tumor, and in which he left the other ovary, which was slightly affected, pregnancy has since occurred, followed by the delivery of a living child

Dr Howard Kelly remarked that Dr Keith had had remarkably good results from the application to oozing surfaces of a solution of pernitrate of iron He has observed the gradual disuse of carbolic acid in washing-waters in operations Dr Kelly prefers boiled or distilled water as used abroad, as he is sure that carbolic acid and other germicides are frequent causes of poisoning and bad results after operation He asked Dr Goodell what were his rules respecting the use of the drainage-tube in operations on the abdominal cavity?

Dr Baer had experimented with Monsel's solution In one case in which he used it he attributed the fatal result to it The coagulation by the iron is unsightly, and he should now consider it a last resort. He had had very good results from pressure by packing sponges against the bleeding points, combined with external pressure He withdraws the sponges at the last moment before tightening sutures, and then bandages the abdomen tightly

Dr Goodell remarked that Dr Montgomery was perfectly right in his defense of the second ovary, and he himself had performed double ovariotomy in only seventeen cases of the twenty eight He did not believe that every ovary studded with cysts would inevitably degenerate into an ovarian tumor So, in the case of slightly diseased ovaries in young married women, he would be disposed either to let them alone or to remove the diseased portion only But in women approaching the climacteric, or when other conditions would make it advisable, he would remove the second ovary as useless in itself and as a possible source of future trouble He has used the drainage tube but three times during the past year, once in the unfinished case of oophorectomy, again in the case of torn bladder, and in the case requiring over thirty ligatures and with universal adhesions In general he uses it when a free oozing of blood is to be expected, but he regards it as a source of trouble and removes it as soon as possible

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

Officers of the New York County Medical Association—The Etiology of Tumors—Library of the New York State Medical Association—The Suppression of Contagious Ophthalmia—An Act for the Better Preservation of the Health of Children in Institutions—Proposed Abolition of the State Board of Health—Annual Hospital Saturday and Sunday Collections

The annual meeting of the New York County Medical Association was held January 18, when the following officers were elected for the ensuing year President, Dr Charles A Leale, Vice-President, Dr John Shrady, Recording Secretary, Dr P Brynberg Porter, Corresponding and Statistical Secretary, Dr Glover C Arnold, Treasurer, Dr E S F Arnold, Members of the Executive Committee, Drs John H Hinton and C S Wood

On this occasion Dr Laurence J McNamara, one of the instructors in the Carnegie Laboratory, read a paper on the *Etiology of Tumors*, which was designed as a study of some of the existing theories on the subject, and an attempt to adapt them to the various forms of tumor which the author had had the opportunity of personally examining In speaking of sarcoma and carcinoma, which, he said, were formed after types of normal tissue, and were most frequently brought to the notice of the surgeon, he mentioned particularly the secondary formations or metastases which are met with in connection with them, and to their tendency to recurrence after removal Tumors based on the type of cartilage tissue, however, had been known to produce secondary deposits also These secondary metastatic or secondary deposits bore the same relation to the structures in which they found a resting-place, as the parent tumors, and assumed the same changes in growth, development and invasion of organs as the primary growth There could be no doubt as to the cells of these deposits coming from the original tumor, and the channels of infection are the lymph and blood In the ordinary cases of carcinoma examination of the advancing mass showed infiltration of the normal tissue by epithelial cells, and in this formation, at least, it was unnecessary, he thought to imagine a virus, transmitted to the body from without, as the cause of the proliferation As regards the malignancy of cancers, the important part lay in the misplaced epithelial cell The independence of these epithelial cells, when removed from their proper resting-place, might be seen in the cases of successful skin grafting

"Place them" he continued, "in the interstices of the loose connective tissue, bathed in the nutrient fluids of the body, and beyond the restraining influences of their own proper tissue, the result must be an increase in activity and development It is not so difficult to imagine the cases in which this infiltration might occur In some cases of breast-cancer which I have examined it seemed that I could make out a distinct connection between the swollen epithelium of the duct and the cells beyond This fact has been mentioned by others The epithelium in the duct and the connective tissue seemed identical in form and appearance"

Cancer, as a rule, seemed to develop on tissue subject to prolonged irritation The most recent changes occurred in the epithelial tissue, but the diagnosis of cancer could not be made until the epithelial cell formed nests in the connective tissue If this epithelial element did not come from the proliferating interpapillary processes, it might exist previously, and to suppose this was to admit the embryonic theory of Cohnheim, which involves the hypothesis of a previously existing element left over from the embryonic state and possessing the power, under favorable conditions, of developing into a distinct tumor When this theory was applied to the carcinomatous group of tumors, it was found that there was no direct proof of their embryonic origin In sarcomatous growths there was more difficulty experienced in accepting this embryonic theory, and until proof could be furnished that these embryonic cells exist in the body and develop into a distinct tumor under favorable circumstances, he was of the opinion that the theory of Cohnheim could not be logically entertained

Later on he said that clinical efforts or experimental works had never been able thus far to connect a bacterium with the cause of tumors They had never been inoculated, and they had never infected the surgeon Still, he thought that the infectious origin of sarcoma at least possessed at present great attractions The discovery of a vegetable growth as the cause of actinomycosis had some bearing on this subject The recent nodules in this affection were made up of small round cells, while epithelial cells and giant cells were found in those more advanced, and these appearances, as in the other forms of infective neoplasms, were due to the inflammatory action of the fungus Sarcoma, when rapidly growing, presented changes of a similar character in the reactive appearance of the cells, but if the growth were caused by a micro-organism, it was necessary to suppose that it was of a nature which requires very favorable conditions for its development

As to the microbic origin of carcinoma he said "It seems to me that the misplaced epithelial elements can account for all of the reactive changes in the cells of the matrix If a micro organism must be considered as the cause of this class of tumors, the question as to why it should affect the epithelial cells alone does not seem capable of explanation There is no evidence that would lead to the belief that it can change the cells of the organism into carcinomatous cells If the latter were true, the lymph glands should be transformed into distinct epithelial tissue" The action of the micro organism, he went on to say, is of an inflammatory character, specific in its nature In carcinoma the inflammatory changes represented the action of the cellular matrix, and the same might be said of sarcoma The hyperplasia of the matrix was but an indication of the efforts of the tissue to cast out or destroy the foreign body

In conclusion he said that it seemed that to no one theory could be assigned the production of these tumor-growths Some of them could account for their formation, as the embryonic theory explained the existence of teratoma The infection theory, while drawing the attention of the surgeon to the malignancy of certain growths, did not have to go outside of the organism and its cellular elements to explain their occurrence

At the close of the meeting the members adjourned to the Library of the New York State Medical Association, where they enjoyed a supper and much pleasant social intercourse The library is also in the Carnegie Laboratory Building, where the meetings of the County Association are held, and, with 35,000 volumes already on its shelves, presents a very attractive appearance

At a recent meeting of the Academy of Medicine the committee appointed last June to take measures, in connection with the representatives of the State Board of Charities, the Society for the Prevention of Cruelty to Children, and the Association for Improving the Condition of the Poor, for the *Suppression of Contagious Ophthalmia* in the asylums and industrial schools of the city and State, made its report through Dr Richard Derby It was stated that a large number of these institutions had been visited, the examinations being conducted by the sanitary inspectors of the Board of Health, accompanied in each instance by experts in ophthalmology Some of the facts elicited are shown in the following extract from the report "The Committee desire, in substance, to say that a worse state of things exists to day in most of the asylums visited than the preliminary report read before the Academy in June last indicated Reports received from various reputable physicians show that in nearly all the asylums of the city children are admitted without due examination of their physical condition, especially as to the condition of their eyes The reports show that the physicians who have charge of these asylums make no systematic inspection of either the buildings or their inmates, that no system at all adequate of quarantine is practiced, and that many of the asylums are grossly overcrowded Besides all this, very grave defects in plumbing have been found To protect the children cared for in the asylums and industrial schools of this State the Committee is satisfied that legislation is needed"

At the conclusion of the report, which contained a large number of details in regard to the abuses existing in the various institutions, as shown by the investigations of the Committee, Dr Derby submitted the draft of an *Act for the better Preservation of the Health of Children in Institutions*, which had been prepared by Mr Elbridge T Gerry, President of the Society for the Prevention of Cruelty to Children This proposed bill provides that every incorporated institution in the State receiving or caring for children (excepting hospitals) shall have attached thereto a regular physician in good professional standing Such physician shall carefully examine each child applying for admission to the institution, and shall give a certificate in writing stating whether or not the applicant is suffering from any contagious or infectious disease, especially of the eyes or skin No child suffering from any contagious or infectious disease shall be allowed to enter or remain in any institution in contact with children not so affected, but shall be immediately isolated or placed in a proper room or infirmary, which shall be provided for that purpose It is also made the duty of the physician to give notice in writing to the officers of the institution whenever any dormitory therein is so overcrowded that there shall be less than 600 cubic feet to each occupant The act was approved by a unanimous vote of the Academy, which also authorized the Committee to have it introduced into the legislature and to urge its passage

The Academy of Medicine has abolished two of its standing committees, that on medical education, and that on ethics, and hereafter the general Council will fulfil the duties pertaining to the latter The last new Section organized in the Academy is one on Orthopædic Surgery

In his annual message Governor Hill recommended the *Abolition of the State Board of Health*, and that its functions should be performed by a single commissioner instead The proposition has not met with much favor, however, and at a recent meeting of the Board of Health of the city of Kingston, on the Hudson, it was suggested that if this measure was proposed for the purpose of saving money, it would be better to abolish the legislature, as the less useful and important body of the two The Governor has very wisely reappointed as Surgeon-General Dr Joseph D Bryant, Professor of Anatomy in Bellevue Hospital Medical College, who has done a very excellent work in this position, and made it something more than an empty name

A short time since a case of small pox occurred in the insane asylum on Blackwell's Island, and 114 of the inmates and attendants were vaccinated Dr Seaman, chief of staff of the Charity Hospital, on the Island, says that that institution, through its system of vaccination, has done more to protect the public health than is generally known For ten years every patient admitted to the hospital has been vaccinated immediately after arriving, and in this way some 50,000 persons have been protected against small-pox

It is hoped that this year the annual Hospital Saturday and Sunday Collections will amount to $50,000, when all the reports have been sent in During the year ending September 30 last, the total expenses of the twenty one hospitals belonging to the Association were $601,801 There was an income from invested funds of $127,099, and from city, county and State appropriations of $29,635 The amount received from contributions other than gifts or bequests to the permanent fund was $201,492, through the hospital Saturday and Sunday collections, $29,917, and from paying patients, $136,403 Total, $524,016 The number of patients treated in the hospitals for the year was 11,969, and in their outdoor and dispensary departments, 109,741 P B P

LETTER FROM PHILADELPHIA

(FROM OUR OWN CORRESPONDENT.)

Election at the County Medical Society—Resolutions in Regard to the International Congress—Dr. Levis's Address before the Academy of Surgery—Col. Waring's Address on the Disposal of Sewage—Discussion on Pasteur's Treatment of Hydrophobia.

The last business meeting of our County Medical Society was, as your occasional correspondent "Spectator" has said, one of great interest. It was an unusually large meeting, because of the anticipated contest over the election of delegates to the State Society, and to the Amerigan Medical Association. It was well recognized that the election of the delegates proposed by the nominating committee would be taken to mean that the Society approved of the action of the Association at New Orleans in regard to the proposed International Congress, and that it endorsed the man who is considered here as the representative of all that that action implied. It was equally well understood that the election of the informally presented candidates would mean that the Society did not approve of what the Association has done, and will not endorse those who furthered it. There was a great deal of excitement at the meeting, and it was apparent that all present felt the importance of the vote which was to be taken. Before it was reached there arose a question of law. On the one hand the rules of the Society were cited, and it was claimed that no candidates could be considered as eligible except those proposed in the usual way by the nominating committee. On the other hand it was replied that, if this were the case the Society would not annually go through the farce of an election, the mere fact of holding an election implying that the voters could exercise a choice at the polls. In addition to this, it was claimed that the list proposed by the nominating committee was but part of a report, and that the Society could treat this report like any other, altering or amending it, as, for example, by substituting other names for those proposed, if it saw fit. Under this claim a motion was put and carried to substitute for the names on the ticket selected by the nominating committee another set of names, the same as were printed on the new list, which had been sent by mail to the members of the Society.

The vote in favor of this motion was about three to one, and showed pretty plainly the sense of the meeting. While the voting was proceeding, Dr. Agnew proposed the following resolutions, which were adopted:

Resolved, That at its annual election of delegates to the American Medical Association and to the Medical Society of the State of Pennsylvania, the Philadelphia County Medical Society desires to express its regret at the action of the American Medical Association at New Orleans, in view of the injurious results which have followed to professional harmony and to the prospects of the International Congress.

Resolved, That the delegates from this Society be instructed to endeavor to procure such modification of that action as may best conduce to the reestablishment of professional harmony and to the success of the Congress.

The result of the election was that the new ticket was chosen by the overwhelming vote of 169 votes as against 36 for the ticket of the nominating committee.

The annual address before the Academy of Surgery was delivered on January 4 by Dr. Levis, who selected for his subject *Impediments to American Surgery*. Of these, he mentioned lack of organized effort, and loss of unrecorded work. In this connection he urged a hearty support of the Committee on Collective Investigation appointed at the last International Medical Congress. He also referred to the reprinting of foreign works at a lower price than native medical works can be produced, and advocated the passage of an international copyright to protect our own authors. The value of the American text-books is to be seen from the fact that, in spite of the influence of local jealousy, in 72 colleges there are recommended to the students 157 American works on surgery as against 186 foreign works, and he mentioned with pride that of the American works there are three more in demand than any others, and these are all by Fellows of the Philadelphia Academy of Surgery. Dr. Levis also made a plea for the encouragement of the labors of men who live at a distance from the cities. He mentioned the achievements of McDowell, Atlee, and Sims, as indications of what may be accomplished at a distance from what are generally regarded as the best places for advances in surgery. A considerable part of the address was devoted to discussing the opposition to experiments on the lower animals. Here Dr. Levis was severe enough on the antivivisectionists.

Within a few days Col. Waring addressed the College of Physicians on *The Disposal of Sewage*. He presented his now well-known views in regard to this matter, illustrating the successful working of surface disposal of sewage by the case of the Norristown Hospital for the Insane, in this State, and on the edge of this city, where the entire sewage is carried, separate from the surface water, through pipes to a tank which communicates with a field 1000 feet feet away, where it is distributed over the surface. By this process the land is fertilized and the sewage is disinfected.

The last conversational meeting of the County Medical Society was occupied with a discussion of the method of treating hydrophobia recently announced by Pasteur. The paper of the evening was read by Dr. Dulles, who gave a summary of all of Pasteur's communications on the subject of hydrophobia, and endeavored to show that the evidence adduced from time to time by Pasteur in support of his various theories does not recommend them very strongly. He laid great stress upon the apparent contradictions of Pasteur's own statements, and the inconsistencies of his conduct, as, for example, when he asserted two years ago that he had a way of rendering dogs refractory to rabies in as large numbers as any one could wish, and yet has not rendered a single dog refractory to rabies outside of his laboratory in all that time. He called attention also to the fact that Pasteur's theories in regard to hydrophobia are in striking contrast to his theories in regard to other diseases which he considers to be like it in nature, such as *charbon*, and chicken cholera. The aim of the whole paper was to convict Pasteur of drawing illogical conclusions from imperfect premises.

Dr. S. W. Gross thought that Dr. Dulles did not do justice to Pasteur, and that he might be assumed to know what hydrophobia is, because there is a large veterinary school near Paris, France, to which he might be supposed to go to study the disease. He also claimed that Pasteur has protected dogs from inoculation with rabies, and it was safe to suppose he might protect human beings. To this Dr. Dulles replied that it might be reasonable to assume that Pasteur knows what rabies is, if he had not put on record some of the symptoms upon which he rests his diagnosis. But, he has done this, and has made it clear that his ideas as to the disorder are much too elastic, and liable to lead to error when applied by such an enthusiast as he is. As to the protection of dogs by inoculation, he referred to the fact spoken of in his paper, that in the past two years this ability which Pasteur claims has proved nothing but a questionable scientific curiosity. The most that can be substantiated for it is that Pasteur seems to be able to fortify the subjects of his experiments against the artificial disease which his virus produces in unvaccinated dogs.

Dr. Wood suggested that there must be a great deal of truth in what Pasteur claims unless we are to suppose his brain is undergoing the inevitable change. To this Dr. Dulles did not agree, saying that a man might be very wise in general and yet mistaken as to a special matter. This he thought to be the case with Pasteur, and he hopes it was not necessary to choose between considering him right in regard to hydrophobia, or crazy. It may be remarked that the sentiment here seems to be that Pasteur's claims are extravagant and entirely unproved, and we have not had any suggestion of the excitement which had been stirred up elsewhere about hydrophobia in animals or in men.

C. W. D.

MEMBERSHIP OF THE INTERNATIONAL CONGRESS.

To the Editor of the Journal:

Dear Sir:—While the International Medical Congress is being so vigorously discussed in the journals, it is possible the rank and file of the profession are being misled as to what was really expected of them by the *Original Committee of Seven*.

Some months ago the *N. Y. Medical Record* published a letter from Professor Hansen Grut, of Hummellaft, Denmark, to Dr. H. D. Noyes, of New York, containing the following statements in reply to inquiries made by Dr. Noyes of him as Secretary-General of the Eighth International Medical Congress, as to the "admissibility of homœopaths":

(3) "The *only* qualification required was that the member be a *legally acknowledged* medical practitioner in his country. *Our* homœopathists, who were legally acknowledged practitioners (Drs. Siemsen, Ferich, and others), were actually members, and undisputed members, of *our* Congress."

Now let us clearly understand what is expected of us. *First*. Is it expected that *our* homœopathists, who are also "legally acknowledged" practitioners in this country (Dr. Verdi, of Washington, member of the National Board of Health, for example), shall likewise have the right to become "actually members and undisputed members" of the Ninth International Congress, as Professor Hansen Grut says was the case at the Eighth at Copenhagen?

Secondly. Is it expected that *their* homœopathists (Drs. Siemsen, Ferich, and others) being "legally acknowledged practitioners" in their country, shall become "actually members and undisputed members" of our Congress, as Dr. Hansen-Grut declares they were of the Eighth?

Thirdly. If homœopathists are thus to be admitted to undisputed membership, is it also expected that the other *legally acknowledged practitioners* of this country, who belong to the eclectic, the physio-medical, the hygeio-therapeutic, and the mixed schools included in the enumeration of the legally acknowledged institutions in the United States, in the Report on Medical Education of the Illinois State Board of Health for 1885, shall likewise be actually admitted?

Now, what the members of the American Medical Association want to plainly understand is, whether the doors of the Congress are to be opened to *all legally acknowledged practitioners* whomsoever in this country. They can then decide at their approaching annual meeting just what to do. Meanwhile, perhaps Dr. Billings, as Secretary of the Original Committee of Seven, can explain what he and his Committee really did expect of the American Medical Association.

A. M. A.

BOOK REVIEWS.

The Physician Himself and what he Should Add to his Scientific Acquirements in order to Secure Success. By D. W. Cathell, M.D., late Professor of Pathology in the College of Physicians and Surgeons of Baltimore. 8vo, pp. 284. Fifth edition. Thoroughly revised. Baltimore: Cushings & Bailey. 1885.

The appearance of a fifth edition of this volume shows that it is well known and its merits fully appreciated. Consequently no extended notice is necessary. The work is more particularly valuable to the younger members of the profession, and cannot be carefully read without interest and profit. Its style is pleasing, and the statements inculcated are ennobling to the moral character, and calculated to inspire a higher sense of the true dignity of the medical profession. The publishers have executed their part of the work in good style.

MANUAL OF DISEASES OF WOMEN By CHARLES H MAY, M D, Late House Physician, Mt Sinai Hospital, New York, etc 8vo, pp 357 Philadelphia Lea Brothers & Co 1885 Chicago Jansen, McClurg & Co

Though there is nothing wrong in the matter of this book—since it has been culled the author tells us, from the works of Emmet, Thomas, and other leading gynecologists—there is nothing to particularly recommend it to the practitioner The student "cramming" for his examinations will find it particularly useful and it seems to have been prepared with this end in view But as we do not believe either in the theory or practice of "cramming" for examinations, we cannot recommend the book

ASSOCIATION ITEMS.

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the JOURNAL for one year from the following July Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

RICHARD J DUNGLISON, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

HEALTH IN MICHIGAN FOR DECEMBER, 1885 —For the month of December, 1885, compared with the preceding month, the reports indicate that bronchitis, neuralgia and pneumonia increased, and that typhoid fever, typho malarial fever and diarrhœa decreased in prevalence Compared with the average for the month of December in the seven years, 1879–1885, pneumonia, remittent fever, typho malarial fever, intermittent fever, diphtheria and consumption of lungs were less prevalent in December, 1885

For the month of December, 1885, compared with the average of corresponding months for the seven years 1879–1885, the temperature was about the same, the absolute and the relative humidity were more, and the day and the night ozone were less

Including reports from regular observers and from other sources diphtheria was reported in Michigan in the month of December, 1885, at sixty five places, scarlet fever at forty-two places, typhoid fever at twenty places, and measles at five places Reports from all sources show diphtheria reported at two places more, scarlet fever at three places more, typhoid fever at fourteen places less, and measles at one place less in December than in preceding month, November, 1885

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JANUARY 16 1886 TO JANUARY 22 1886

Major Warren Webster, Surgeon, sick leave of absence further extended nine months on account of sickness (S O 15, A G O, Jan 19, 1886)

CORRIGENDUM

FAGGE S PRINCIPLES AND PRACTICE OF MEDICINE —In a review of the first volume of this work in THE JOURNAL of January 16 1886 page 83 second column last line for idea read *index* To say that this volume is without an idea would be far from true and was equally far from the intention of the reviewer It is hoped that the mistake was evident as only a few line above it is said that with the exception of the matter of treatment 'the book is almost cyclopædic in the information contained in it

COCAINE IN HAY FEVER

Lecture Delivered at the Chicago Medical College,

BY SETH S BISHOP, M D ,
SURGEON TO THE SOUTH SIDE FREE DISPENSARY AND TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY

Gentlemen —America has probably a hundred thousand sufferers from hay fever, a number about four times that of the standing army Any information relative to this subject, especially if it offer a ray of hope of relief or cure, is eagerly sought by this vast army of unfortunates After several years' study of this disease I shall endeavor to present a correct account of the present status of our knowledge concerning its pathology and treatment The several names which this affection bears are unfortunate ones, inasmuch as they do not adequately express its pathology, symptoms, or causes The pollen of grasses, weeds and flowers, and the heat of summer, are but a few of the large number of exciting and predisposing causes

If I were to invent a name for it, both simple and expressive of the nature of the disease, I should call it nervous catarrh I do not know that it has ever been called by that name, but it has not been generally conceded, until recently, that the malady was essentially a nervous one Perhaps a better name than the one I propose could be found, if one should insist that technical terms only, such as neurasthenia, should be admitted into medical nomenclature But nervous catarrh is an expression which would indicate both the true nature of the disease and the prominent symptoms which characterize it The term hay fever does neither, for while hay, in common with many other kinds of pollen, dust, fumes, gases, and so forth, may excite attacks, many suffer from paroxysms into which neither hay nor fever enter as a factor, either causative or symptomatic

In my first efforts to gather information on this subject I discovered that hay fever was considered a conundrum by a part of the profession and a myth by the remainder By the paucity of the literature of the subject it was evident that medical authors did not mean to write most concerning that of which they knew the least From the time of Bostock's discovery of the disease in 1819 to the year 1876, the nature of this affection seemed to be but ill-understood In the light of the accumulated knowledge of the past ten years, however, it seems to be well established that its proper classification is among the neuroses During my first experience with this intensely distressing disease, I followed Helmholtz's suggestion to destroy the vibrio-like bodies which inhabited the nasal secretion, and which he supposed caused the attacks, by the inhalation of a nebulized solution of quinine This gave relief I next tried the effects of administering the same drug internally, and was rewarded by even more satisfactory results Certainly the infusoria in the nasal secretion were not destroyed by the internal use of half a dozen grains of quinine a day

The susceptibility must exist in the nervous centres as well as in the end organs of the nerves Otherwise there is left no rational explanation of the fact that heretofore internal medication by nerve tonics and sedatives have proved more serviceable than local treatment This conclusion seemed to be verified by the fact that it had been demonstrated that a severe catarrhal condition of the nasal mucous membrane followed ablation of the spheno palatine ganglion, which shows the intimate relation sustained between that sympathetic nervous centre and the nervous supply of the mucous membrane involved Branches from this ganglion are distributed to the lining membrane of the nose, soft palate, and the end of the Eustachian tube The motor root of this ganglion is derived from the facial, and the auricular branch of the pneumogastric nerve unites with the facial Thus is established an intimate connection between the nervous supply of the nose, throat, Eustachian tube, larynx, and bronchial tubes, and the explanation of the occurrence of aural and asthmatic symptoms as the result of nasal irritation is made clear It becomes evident, then, if we study the disease from anatomical, physiological and clinical standpoints combined, that there is but one theory which satisfactorily reconciles all the known facts According to that theory three conditions are requisite to the existence of a paroxysm of hay fever First, abnormally sensitive nerve centres, secondly, a hyperæsthetic condition of the peripheral extremities of the nerves, and thirdly, the presence of one of a vast number of irritants

The truth of the first proposition is evident from the fact that it is the only one which satisfactorily explains why but few individuals are affected, out of a large community, all the members of which are alike exposed to the same irritating ingredients of the atmosphere, why ablation of the spheno palatine ganglion causes a severe catarrhal condition of the nasal mucous membrane, why nervous depression, or exhaustion (neurasthenia) predisposes to hay fever attacks, why tonics and sedatives to the central nervous system alleviate, abort, or prevent attacks, why sudden mental excitement may prevent an impending paroxysm, or abbreviate one after its onset, why the disease generally attacks one at precisely the same time, lasts the same length of time, and disappears at the same time on each recurring season, why the class of people who suffer from this affection are the nervous, brain-working type, instead of the phlegmatic, slow going kind, who may be more exposed to the pollen of the field or the dust of the work-shop and street, but whose minds are strangers to the nervous stimulation and mental tension of the professional man, why the paroxysm is as sudden in its invasion as asthma, striking one *at any moment of day or night, awaking one from* sound slumber, or taking one unawares during the pleasant engagements of the day, and leaving one as quickly and mysteriously as it came

Moreover, some functional nervous diseases are transmutable, one into another I have witnessed cerebral hyperæmia decline and disappear as hay fever superseded it, and after several years' duration the hay fever has in turn been displaced by asthma, as spasmodic and characteristic in its nature as the hay fever itself Simple asthma may not only supplant, but may complicate it, constituting hay asthma proper

An error which has been as popular as the Helmholtz theory is the supposition that this affection is necessarily limited to any particular season The enervating effect of extreme heat in summer is an important predisposing cause, as affecting the nerve centres, but in the colder seasons the depressing effect of the heated atmosphere of overcrowded, ill-ventilated rooms, and any causes which render the nerve centres more sensitive, and consequently less able to resist impressions from external irritants, are also provocatives, and bear the same causal relation to hay fever as does the heat of summer

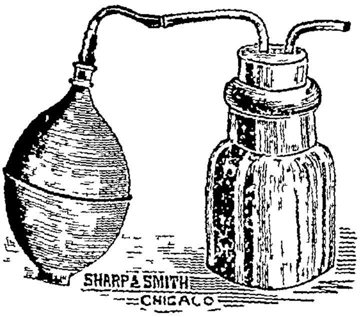
In stating the second condition, it will be noticed that I have not limited the hyperæsthetic condition of the peripheral nerve fibres to those which terminate in mucous membrane alone To demonstrate the correctness of my implied hypothesis it is necessary only to cite those cases in which paroxysms are produced by the rays of the sun, or other bright light, irritating the retina, or an attack provoked by irritating the scalp with a comb, or shaving the upper lip, or a draught of cold air chilling the back of the neck, or hands, or feet A reciprocal relation exists between the capillary circulation of the skin and that of the internal organs, but more especially affecting the mucous membrane lining the air passages Let the surface of a hay fever patient become chilled, the skin anæmic the perspiration checked, and immediately there follow a corresponding hyperæmia of the mucous membrane of the respiratory passages, an increased activity of the muciparous follicles, exquisite tickling and painful itching in the nose and pharynx, succeeded by violent sneezing, profuse discharge of nasal mucus, suffused and tear bedimmed eyes, photophobia, a rush of blood to the head and face, severe headache, complete occlusion of the nostrils, nervous exhaustion, and such a desperate shaking up of the whole being as is comparable to a wrecked vessel in a terrific storm But in this violent agitation of the body I have discerned a blessing in disguise, for it restores the balance of circulation to the skin, the temperature rises, the sudoriferous glands resume their activity, and the skin is again bathed in perspiration At this juncture the vicarious suffering of the respiratory surface is relieved and the normal equipoise of functional activity ensues In one who suffers from the asthmatic form of hay fever, to the symptoms already enumerated should be added the characteristic symptoms of asthma proper These alone make one's lot hard enough, but when added to the so called aristocratic disease, *present a highly colored picture of the refinement* of torture

The truth of the third proposition is self-evident, and the number of irritants, such as pollen, dust, matches, and so forth, which directly excite attacks, would be too extended to enumerate

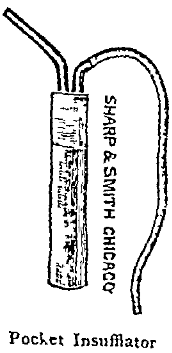
The treatment of hay fever is preventive and palliative No curative treatment has heretofore been discovered The preventive treatment has compelled sufferers to become fugitives from the air breathed by common mortals, and to seek mid ocean or the tops of mountains in their seasons of distress The most important palliative remedies are quinine, chloral, and morphine internally, and quinine, chloroform, and carbolic acid by inhalation In my experience quinine has given more relief than any other remedy, but there is great danger of impairing the hearing by the use of large and frequently repeated doses, for it causes congestion of the middle ear, and probably of the labyrinth The ideal curative treatment would be that kind which addressed itself to the seat of the disease, which resides in the central nervous system Narcotics are the only known remedies which render it entirely oblivious to the presence of the many harassing irritants which insist on being recognized, and which appear to have the same relation to the nervous centres that persistent office seekers do to the President But since it might be objectionable to keep patients in a comatose condition during the weeks or months of their hay fever seasons, the only medicinal treatment left to our choice is that which affects the peripheral termini of the nerves

Cocaine has grown, mushroom like, into a wonderful popularity Let us hope that its usefulness in hay fever may not prove as ephemeral as its growth Unfortunately, those drugs which are most influential for good are also most disastrous in their effects *when their use is not directed and limited by skill* Cocaine is no exception to this rule, and the sooner the knowledge of its harmful properties is widely disseminated the better it will be for all who may have occasion, or invent an excuse, for its use Serious results have attended its use in the nasal cavities Being a powerful local anæsthetic, its advent has been hailed with enthusiasm by all that large class of sufferers whose sensitive mucous membranes make them miserable. Many who used cocaine during their attacks last summer believe themselves to be cured. But let us look facts fairly in the face and state candidly truths which we cannot evade if we would. Can we expect the cure of a disease, the perpetuity of which seems coextensive with the subject's life, by a remedy the effects of which are transitory? The rapidity of action and the intensity of analgesic power of cocaine are indeed remarkable, but its benumbing effect lasts but one or two hours, or less. In order to extend its influence over a considerable number of consecutive hours or days, it is necessary to repeat the applications of a four per cent solution as often as once in an hour or two, and even at briefer intervals. The consequence is an absorption of so large a quantity of the drug as will produce its physiological and even toxical effects. This, together with the fact of its evanescent character, would seem to render it highly improbable that cocaine will ever prove to be a cure for hay fever. As a palliative it acts like magic in some cases. At first I employed a four per cent solution of the hydrochlorate, applying it to the sensitive points by means of surgeon's cotton twisted on a holder. That failed to relieve, and excited paroxysms of sneezing. This result was due to the fact that too little of the solution was conveyed to the parts. Afterwards I used the same solution with a camel's-hair brush taking pains that the parts were first thoroughly cleared of mucus, and immediate relief was obtained. A two per cent solution has often proved effective.

I have more recently used a six per cent powder of cocaine and sugar of milk, in an insufflator which I have devised for hay fever patients, for self treatment. The instrument is small enough to carry readily in the vest pocket, and can be used easily the instant an attack seems imminent. The insufflator consists of a two drachm vial with a stopper through which pass two vertical tubes. These do not extend below the under surface of the stopper. Above it they are bent in opposite directions. To one of these bent extremities is attached a rubber tube, to the free end of which the mouth is applied. A slight puff of the breath is sufficient to send the powder through the opposite tube into the nasal cavities, when the instrument is in position. The tubes should be made of vulcanite, and the vial should not be more than two thirds full. The instrument is constructed after the plan of my larger office insufflator, except that in the latter a rubber bulb supplies the place of the mouth. This method of applying cocaine in powder is simple, effective and easily practiced even in public assemblages, without making one feel offensively conspicuous. I may dismiss this part of the subject by remarking that many cases have been wonderfully relieved by this treatment. In compliance with the request preferred by some of you, I shall speak of its general as well as its topical effects.



Office Insufflator



Pocket Insufflator

When applied to the mucous membrane of the nose, a four per cent solution produces, in a few seconds, a sense of numbness which grows more marked as the applications are repeated. If they are renewed at intervals of five minutes for fifteen or twenty minutes, at the expiration of that time the mucous tissue may be cut or cauterized without any well defined sensations, unless the instruments enter very deeply into the sub mucous tissue. If sensations and pain return soon after an operation it may be obliterated again by a fresh application. Very soon after cocaine has been applied, the membrane looks pale and turns almost white, so anæmic does it become. It retracts in a marked manner even if it were swelled before the application. But I have repeatedly observed a still further effect which I have not seen mentioned in any account of the action of cocaine. Although its primary action produces anæsthesia and anæmia of the membrane, there occur secondary effects which will materially impair or destroy its usefulness in some cases. These secondary effects are great swelling and hyperæsthesia of the parts treated, and these symptoms are even more prominent than they were before the drug was applied. This unhappy result I observed in the treatment of a severe form of hay fever, and in consequence of the augmentation of all the symptoms after the effects of the cocaine wore off, I was compelled to abandon that treatment. Several cases have come to my knowledge in which this action of cocaine has ensued. It seems to act upon the vaso-motor nerves, independently of the central nervous system. The blood-vessels are at first constricted, then dilated, and generally resume their normal calibre. In the exceptions which I have mentioned the dilatation remained for hours, and in one case persisted for a number of days, accompanied with varying degrees of hyperæsthesia. The latter symptom was very acute for several hours succeeding the anæsthetic effects, but gradually diminished until the membrane became no more sensitive than it was before the treatment. The secondary swelling closed the nostrils so completely that no air could be forced through them. In sleep it was necessary to breathe through the mouth, which occasioned extreme dryness of the throat. The breath had to be held while eating, and with every act of swallowing the air was forced into the Eustachian tubes, and even particles of food seemed to take the same course. No one can realize the importance of open nasal flues until he attempts to eat, sleep or talk with them closed. Cocaine would relieve this secondary tumefaction temporarily, but it would return after each application. Fortunately there seem to be but few who are so peculiarly affected by this remedy I have employed it in many cases of various diseases in which I have observed no disagreeable consequences and shall be glad to relate the gratifying results obtained at another time

The physiological and toxic effects are somewhat similar to those of theine and caffeine Cocaine is a powerful poison affecting the nervous, respiratory, circulatory and vaso motor systems In small doses it is a prompt and decided cerebral and cardiac stimulant without inducing coma The pulse and respirations are accelerated, the intellectual processes quickened and exhilarated, and the mental vision delighted with agreeable hallucinations Diplopia, constipation, muscular tremors, vertigo and nausea are a series of symptoms attending larger doses Still larger doses produce contracted pupil, complete paralysis of sensibility, tetanic spasms, and death It does not produce muscular paralysis, but does paralyze the entire posterior columns of the spinal cord, and the entire system of peripheral sensory nerves Accounts of cocaine poisoning disagree as to the condition of the pupils In some cases they are said to have been widely dilated, in others contracted, as in opium-poisoning Cocaine placed in the eye dilates the pupil widely However, cocaine poisoning simulates opium poisoning so closely that the former has been mistaken for the latter and treated for opium poisoning, with recovery

The new surgical treatment of hay fever, which consists in cauterizing the sensitive areas, is too recent to have afforded permanent results Not wishing to prejudice against the operation those to whom it might prove beneficial, I willingly part company with this phase of the subject But I cannot do so with fidelity to the profession and to this class of patients without warning them of possible consequences This treatment may precipitate paroxysms of veritable asthma In fact, two applications of the galvano cautery, under cocaine anæsthesia, have superinduced true asthma without curing the hay fever

He who finds a cure for this disease need take no thought for the morrow, for that great army of sufferers would cast their golden treasures at his feet, and profession and people alike would erect to his memory a monument more enduring than bronze and more lasting than stone

EXPERIENCES WITH THE AXIS-TRACTION FORCEPS

BY T FELSENREICH, M D ,

DOCENT OF MIDWIFERY AND GYNÆCOLOGY IN VIENNA

I consider it very fortunate that the years of my service as assistant just coincide with the time in which great progress was made not only in gynecology, but also in midwifery The thorough use of antisepsis, the entire reform of the *sectio Cæsarea* by the method of Porro, the modification of the forceps for the higher-lying head, suggested by Tarnier, the prophylaxis against *blennorrhœa neonatorum*, took place in the short period of six years, during which I was clinical assistant By this circumstance I had the opportunity to study these points in an exact manner, alone and with colleagues, as it is not possible to do in private practice

I operated originally with one of the first patterns of Tarnier's forceps The result was then bad both for mother and child But we had chosen severe cases, very wrongly, for this is the way to discredit even a good and useful method in the first stage of its development But even these experiments with Tarnier's[1] complicated forceps were sufficient to prove thoroughly the correctness of his principles For Vienna it was principally important that Prof Gustav Braun should come to the same opinion and decide to follow the further modifications of this forceps and to try their value Without G Braun we probably should not know about the axis traction forceps practically more than that which Kucher imparted to us The adversaries of Tarnier and his principles were to be found among the older and younger obstetricians Many of them condemned his forceps, and condemn it still, partly without knowing what the matter in question is, though French, English and German physicians have tried to cultivate Tarnier's ideas, and the patterns have become more and more simple and serviceable The same fate befell the simple prophylaxis against *blennorrhœa neonatorum* An assistant who had been during several years in service, declared five years ago that he knew a clinic where no *blennorrhœa neonatorum* could be found, although the prophylaxis had not been introduced at that time Only the method of Porro found universal approval here

In spite of these adversaries, A R Simpson's axis traction forceps found here in Vienna a place where they were impartially tried When I first saw the forceps the delicateness of the blades and the spring like consistence of the material struck me A pair of forceps, devised especially for a head which is out of proportion or high lying, ought to have at least the same firmness and the same size as the common forceps The otherwise very simple construction of the axis-traction forceps, and the employment of the form of our "Schulzange" (by J Y Simpson) in the construction of it, induced Prof C Braun to allow experiments with it I operated (February 24, 1882) with A R Simpson's forceps the first time in his presence, and with very satisfactory result

Case —Prot No 536, 1882 The woman, 33 years old, III-para Outside, the forceps had been tried twice, without the child being extracted Flat pelvis, *conjugata vera* 8 cm The exhausted uterus was sunken to the right side The tympanitic percussion sound reached up to the linea alba Temperature and pulse normal The heart-beats of the child accelerated, the head fixed, its greatest circumference above the *conjugata* A large *caput succedaneum* The *os uteri* nearly fully dilated Disinfection, narcosis Alexander Simpson's axis traction forceps Easy operation with few tractions Moderate atony of the uterus and hæmorrhage, caused by the necrosis. Disinfection, massage, ergot.

---

[1] The recent patterns of Tarnier must be simple and good as Das seige has altered decidedly his opinion about this instrument

Child living, weight 3500 grm. Patient was discharged as usual on the eleventh day. The mother got pleuro-pneumonia without connection with the puerperium, and left the hospital healthy on the 17th of March.

Dr. Pritze and I operated with this instrument in six other cases. Four were small pelvis cases, head in all cases high up and fixed. In the two cases with normal pelves the children were large, the one (4270 grm.) profoundly asphyxiated, the reanimation was not successful, the other (4400 grm.) was born living. In two cases the extraction with A. Simpson's forceps was vainly attempted, so that craniotomy was done. In one case (normal pelvis, child 4270 grm.) the head was drawn with the axis traction forceps down to the perineum. At the exit of the head the instrument was about to slip off, so that the last part of the extraction was performed with C. Braun's forceps (J. Y. Simpson's forceps, obliterated fenestræ and handles, covered with hard rubber). In another case the button on the right traction rod was broken during the tractions, so that the operation was finished with the common forceps. Three children living, one asphyxiated, two still born (craniotomy). Three puerperia passed normally. Three women became ill with a light encolpitis, but were healthy when discharged.

These trials with A. Simpson's forceps and the complaints about their faults became apparently known in Edinburgh, so that someone had the extraordinary kindness to send me from there a much more solid instrument, for which kindness I now find the opportunity to express publicly my thanks.

The sixteen cases mentioned by A. R. Simpson in his paper on the axis-traction forceps include only two cases of narrow pelvis. Therefore it was not possible to try sufficiently the instrument in cases for which it had been devised, viz. on the high lying head. With a larger number of cases of narrow pelvis A. R. Simpson undoubtedly would have got the opinion that the forceps only sufficed for the lighter cases, but that it cannot cause the head to accommodate itself to the disproportion of the pelvis. He should have combined the axis traction apparatus with the forceps of J. Y. Simpson, as firmly constructed as the Viennese pattern ("Schulzange"). In this way he would have got a well constructed and reliable instrument.

The disadvantage of the fixation screw is usually exaggerated. Drawing the screw too close naturally causes damage, as well as the violent compression of the gaping handles of the common forceps, if they are adjusted to the high lying head. It is not necessary to mention that one must loosen the screw and the handles of the forceps during the pauses between the tractions, just as it is the rule in using any other forceps. The head recovers from the compression under otherwise favorable circumstances. The screw is only to effect the fixation of the forceps and not the compression of the head. It is therefore constantly controlled by the exploring hand, and is at first only slightly drawn.

For the extraction with the axis traction forceps only one hand is required. If the power of one hand does not suffice for the traction, this shows, according to my experience, that there is such a disproportion that the operation with forceps cannot result favorably to mother and child. The successful traction with only one hand is the best proof that much power is spared in using the axis traction forceps in consequence of the proper direction of the traction. This is also the best affirmation and proof of the correctness of Tarnier's ideas. Even the most skilful operator, who best knows the pelvis, cannot estimate all factors which are called in question and often incessantly change (the narrowness and shape of the pelvis, the size, hardness, position and accommodation of the head). Therefore he cannot constantly draw his instrument in the axis of the pelvis. If we wish to follow the latter surely and avoid every injurious direction of the traction, we must resort to a pair of forceps which find so to speak, the shortest way through the pelvis by themselves, and which leave to the head the greatest liberty of movement during the tractions. By this circumstance the head attains in its progress through the pelvis a certain independence of the direction of the traction. This is attained in a different degree by the axis traction forceps, the name of which appropriately was changed by Breus[*] to "pelvic entrance forceps."

The usefulness of the axis traction forceps of Alexander Simpson for the extraction of the head fixed at the entrance of the pelvis was proved to me after the first trials to be sure, only by using a firmer and more safely constructed pattern. The traction contrivance was, on the contrary, for the pelvic-exit nothing but a disagreeable addition. Like Sanger with the forceps of Busch, I had the intention of transforming our firm, excellent "Schulzange" of J. Y. Simpson in such a manner that they would not be changed in their approved form for the pelvic-exit, but that they could be changed into an axis-traction forceps after A. Simpson's pattern by affixing the traction rods to them. In this manner they could afford also the advantages of the latter forceps.

Executing this intention I came, when I interrupted my clinical activity, only to the first pattern, after which several specimens were constructed by Leiter in Vienna. The adjoined diagram, taken from Leiter's catalogue, releases me from giving an exact description. The size and the proportion of the parts are perfectly equal to those of the forceps of J. Y. Simpson. It is important that the traction rods should only be made from one piece of steel. They have nowhere a soldering. If this be not the case, they would not accomplish their purpose, and would easily break at the operation, as it happened to me with the upper button of one traction rod. The fixation of the traction rod on the blade of the forceps by the simple metal button is on this first pattern still too loose and too unsteady. Also the curvature of the traction rods is unnecessarily strong and could be flatter as in Sanger's forceps. The joint of the traction-rods consists of two metal grooves, in which the two button-shaped ends of the traction-rods are attached This really very simple manner of forming the traction rods I should like to have changed in another pattern, perhaps by the contrivance of Tarnier, as it is brought in use again by Dr Neale Certainly this gives more firmness to the traction apparatus Also the endplate of Sanger's[3] instrument could perhaps be used, if one would correspondingly change the ends of the traction rods In short, it would be necessary to change much before one could advise the forceps for common use Therefore I omitted a description and added to the diagram in Leiter's catalogue a direction for use which may follow here literally in order to make the report complete

FORCEPS AFTER SIMPSON, MODIFIED BY FELSENREICH

The axis traction forceps were constructed with the intention to give to every skilful obstetrician the possibility of using such an instrument on the high lying head, without requiring another forceps for the common cases The forceps consist of the common forceps of J Y Simpson, a compression apparatus *s*, two traction-rods, which can be attached at *o*, and a transverse handle grasping the traction rods at *k*, which is movable to the sides by a joint at *g*

DIRECTIONS FOR USE

1 One may use the forceps without compression and without traction-rods in the manner till now used for the head (face or vertex), being on the perineum or in the middle of the pelvis

2 If the head is high up, each blade is mounted with the proper traction rods, this is taken with the handle of the blade, and the blade is then applied After having applied the right blade one pushes its traction rod over the left handle Then the compressorium and the transverse handle is attached, with which one makes the test traction and the tractions themselves One follows in the direction of the tractions the movement of the solid handles and adheres closely to them

3 One must avoid a too strong compression of the head and must open the screw between each traction

4 This instrument does not extend the indication for the use of the forceps on the high-lying head One must be warned of using more power Generally the pull of one hand suffices

I operated with this instrument, which is, as I mentioned before, in many respects imperfect, in five cases, four times in cases of narrow pelves The shortest *conjugata vera* was 8 cm Three children were born living, two asphyxiated On child was reanimated and could be dismissed healthy on the tenth day The other died the day of the extraction in spite of reiterated trials of reanimation The weight of the children was 3350–3750 gram The puerperium of the five mothers (one primipara and four multiparæ) was in every way normal Four mothers were dismissed at the same time with their children

The number of the cases is small, but the results for mother and child very good The circumstance that the children were living shows certainly that the compression screw, if correctly used, is not dangerous The name compression screw is unluckily chosen, better is fixation-screw The use of the first name itself would cause a prejudice In spite of these favorable results for mother and child I cannot advise the instrument for common use Only a skilful and cautious operator will find the right measure in every respect, and the instrument requires a constant control The construction of the pelvic entrance forceps by Breus is simpler corresponding to its special purpose One can better advise this forceps for a common application Also, with this forceps, as with all similar instruments, the operator must moderate his powers very much The forceps is not constructed to overcome every obstruction caused by disproportion One can hurt mother and child with too much force applied in the right direction as in other cases, only perhaps in another place I have seen infraction of the parietal os on the head of the child after the use of a pelvic entrance forceps, because the forceps trial had been extended too far Every good thing turns, if used immoderately, to bad

The difference between the modifications of Felsenreich and Neale are not great, and certainly not essential By my communication, which would be otherwise useless, Dr Neale learns the advantages and faults of his and my instrument, so that he perhaps will be able to avoid the latter and to devise a pair of forceps which are proper both for the pelvic-entrance and the pelvic exit If he succeeds, then he has certainly fulfilled a want of the practical physician, for our instrumentarium scarcely allows an increase by a separate pelvic entrance forceps I would congratulate him with pleasure, and would be very glad that his sojourn at the University of Vienna should bear such beautiful fruit Dr Neale's industry and zeal for gynecology will always remain a very pleasant memory

Vienna, December 6, 1885

INTUBATION OF THE GLOTTIS FOR MEMBRANOUS LARYNGITIS

BY E. FLETCHER INGALS, M.D.,

PROFESSOR OF LARYNGOLOGY IN RUSH MEDICAL COLLEGE, AND PROFESSOR OF DISEASES OF THE THROAT AND CHEST IN THE WOMAN'S MEDICAL COLLEGE, CHICAGO.

Considerable interest has recently been excited in the profession by reports of several cases in which tubage or intubation of the glottis through the natural passages has been practiced as a substitute for tracheotomy. We are indebted to the ingenuity and persistence of Dr. Joseph O'Dwyer, of New York, for the instruments with which this operation is performed, and for the first practical use of this novel procedure, though several before him have experimented in the same direction. We are further indebted to Dr. F. E. Waxham, of this city, for his enthusiasm in trying the new method, which has brought it fairly before the profession. With unusual modesty Dr. O'Dwyer seems to have experimented a long time before any outside of his immediate circle of acquaintances knew of his efforts, it being his desire to perfect the instrument before publishing his results.

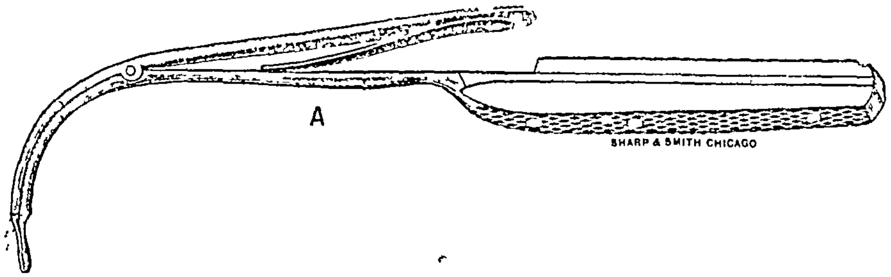
In April, 1885, Dr. Waxham procured a set of Dr. O'Dwyer's instruments, and he was so encouraged by his success that he has used them to the exclusion of tracheotomy until he has treated a number of cases by this method, eleven of which he has published. At the time of his last writing two cases had recovered and two others were apparently convalescent. His experiments demonstrate that there is a field of usefulness for the new operation, especially among very young children.

Recently Sharp & Smith, of this city, obtained for me a set of Dr. O'Dwyer's improved instruments, which I have used in two cases. The first of these was a child about two years of age, to whom I was called by Dr. A. M. Stout. The child had been suffering from diphtheria for several days, and when I saw it had passed into the third stage of diphtheritic laryngitis. There was lividity, constant dyspnœa, stridor and inspiratory retraction of the softer portions of the chest walls. As we could get no assistance, Dr. Stout held the child while I introduced the tube, which was done with little difficulty. After five or ten minutes breathing became easy, the patient seemed perfectly comfortable, and it soon fell into a natural sleep. The relief here was as great as would have been obtained by tracheotomy, and the subsequent course of the case was the same, in all probability, as it would have been if the trachea had been opened. Breathing continued easy for about thirty-six hours, then there was a gradual failure of the respiratory function. The child died easily about forty hours after the tube had been introduced. There had been no choking in the meantime. The tube was removed, after death, and found perfectly free.

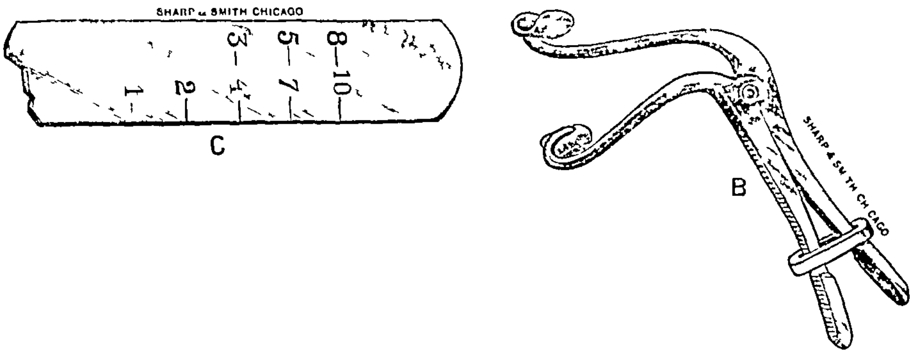
The second case was a strong boy about five and a half years of age. The parents had, two or three years previously, lost one child from membranous croup, and therefore were anxious to do all they could to save this one. The boy had been taken with croupy symptoms a day or two before I saw him. I found the eyes bright, the skin bathed in perspiration, cheeks, lips, and nails becoming livid, and recession of chest walls. The pulmonary signs were normal, and there was no evidence of diphtheria. Had the environments been good, I should have expected to save this patient by tracheotomy, but owing to the poor surroundings, and the certainty of poor nursing, we decided in favor of the new method. I accordingly introduced a tube, 2¼ inches long, such as is recommended by Dr. O'Dwyer for children of this age. The breathing was immediately relieved, and after about ten minutes became easy, though, owing to the small calibre of the tube, it was not so free as in health. At the time it seemed to me about seventy-five per cent. better than before the tube was introduced. Dr. Todd reports that for about twenty hours the patient was cheerful and breathing comparatively easy, but later the breathing became more rapid, numerous mucous râles were heard over the upper part of the chest, the pulse, which had been nearly normal, became feebler and more frequent, and matters grew steadily worse until the child died about thirty-nine hours after the tube had been introduced. Dr. Todd says, "I think that life was somewhat prolonged and the suffering considerably mitigated by the intubation." In the first of these cases the result was as good as I could have expected, but in the second I believe that a proper opening in the trachea would have greatly improved the child's chances if it could have been properly cared for after the operation.

I have seen reports of only five of Dr. O'Dwyer's cases, two of which, aged respectively 3¼ and 3½ years, recovered. It is too early to judge of the actual merits of this operation by the results in the few cases published, but they clearly demonstrate its practicability and no small degree of usefulness. I believe that for children under 3½ years of age it is preferable in nearly all cases to tracheotomy, but for older children the tubes thus far furnished are not large enough to admit a sufficient quantity of air, and therefore in severe cases life may often be lost when a timely tracheotomy would have been successful, but notwithstanding these objections, the ready consent to this operation where tracheotomy would not be allowed, the ease with which the tubes may be introduced, and the freedom from danger in the operation itself, render this procedure, as it seems to me, a most important advance in the treatment of diphtheritic laryngitis and membranous croup. Often parents would not consent to having the child "cut," as they express it, who would at once assent to this method. Often there are circumstances which induce or compel the physician to defer tracheotomy until it is too late, in which cases, if this method were employed, several hours might be gained, and then, if necessary, tracheotomy might be performed.

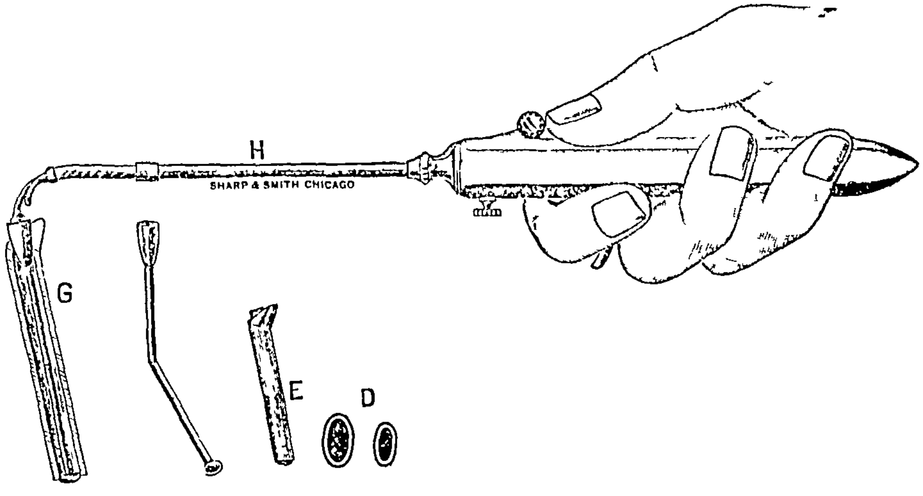
The ease with which the operation may be done will prompt its early adoption, and thus carbonic acid poisoning may often be avoided, and doubtless the extension of the disease thereby materially lessened. Again, many who might well hesitate to attempt tracheotomy need not hesitate to introduce one of these tubes, for with a knowledge of anatomy which all physicians are supposed to possess, and with reasonable care not to exercise too much force and to use due dispatch, no possible harm can come What though the tube were introduced several times into the œsophagus, it could be easily withdrawn by the attached thread, and it might finally be lodged in its proper place There appears to be very little danger of the tube slipping through the glottis, and even if it should it is so long (reaching, as it does, to within half an inch of the bifurcation of the trachea), that there would be no special danger from it, and if it could not be removed *per os* it might readily be extracted after tracheotomy



A—Extractor Half size



B—Gag Half size *C*—Gauge actual size excepting that the end is shown broken off The distance from the end of the tube to the line 10 is 2½ inches



E, F, G and H half size
H—Applicator screwed into the obturator, which is in the tube *G* ready for insertion The artist however has made a mistake and shown the tube *G* with its back edge in front. *E*—Smallest tube bulging on the sides at the middle *F*—Obturator *D*—Actual size of the opening in the largest and smallest tubes

Dr O'Dwyer's set of instruments contains a gag, five laryngeal tubes, an applicator, extractor, and a gauge The gag for keeping the mouth open is all that is needed for very young children, but it does not open quite wide enough for children over three or four years of age There are five laryngeal tubes, which range in length from 1¾ to 2½ inches The calibre of the largest and smallest of these is shown in the cut, and is seen to be only ⅛ × ¼ of an inch in the largest, and not more than half this capacity in the smallest Each tube has at its upper extremity an eye for the silk thread used when it is being introduced There are jointed obturators which fit each of these tubes and hold them while being introduced They are jointed in order that they may be more readily withdrawn when the tube is in the larynx The rounded lower extremity of the obturator is of a size and shape to perfectly close the opening in the tube, and prevent injury to the soft tissues during its introduction Its upper extremity has a small hole, into which the applicator is screwed when the instrument is ready for use The applicator is shown in the cut with the obturator partially screwed on The stem of this instrument is covered by a sliding tube which, when the laryngeal tube has been inserted, may be crowded forward by the thumb piece to release the obturator so that it may be withdrawn, and leave the tube in position The instrument for removing the tube is constructed on the principle of a dilator In using it the closed blades are passed into the end of the tube, the lever is then pressed down by the forefinger, when the opening blades impinge so firmly against the sides of the tube that it is held securely This has been found more convenient than the forceps which were first employed, and it has the additional advantage that it cannot injure the soft tissues The gauge is designed to determine the size of the tube to be used in a child of any given age

In performing the operation the child should be wrapped in a sheet or shawl, which will pinion the arms, and then held upright in the nurse's lap An assistant holds the child's head The gag is then introduced between the jaws, far back on the left side of the mouth, and opened as wide as need be, but not with great force The physician, sitting in front of the patient, passes his left index finger over the base of the tongue and down behind the epiglottis, and with it guides the end of the tube into the glottis

Dr O'Dwyer recommends that the handle of the applicator be held near the child's sternum until the end of the tube has reached the pharyngeal wall, but I think it will usually be found more convenient to hold it to one side The end of the tube having reached the pharyngeal wall, it is directed downwards and forwards along the index finger into the larynx This will not be found difficult, but the infant's epiglottis is so small and flaccid that the operator may not be able always to recognize it, though he will have no difficulty in detecting the larynx as a whole, which, except that it is slightly irregular, feels much like the end of one's little finger The operator should not expect to detect the opening of the glottis, but must be guided by his anatomical knowledge to pass the tube into the centre of the larynx Unless he is careful to carry the handle of his instrument high and thus bring the tube as far forward towards the base of the tongue as possible, the tube will be passed into the œsophagus While it is desirable to accomplish this portion of the operation as quickly as possible, it should not be done with too great haste Ten or twenty seconds, which is a long time for this portion of the operation, may be taken without danger If the tube is not then introduced it should be removed for a minute or two to allow the child to breathe, and then the operation may be repeated, but if the tube seems to be in the proper position, whether the operator is certain of it or not, the slide should be crowded forward so as to disengage the obturator, which is then withdrawn Some cough will occur at once, and if the tube has not been inserted into the larynx, or if it has not been passed down so that the rim rests on the vocal cords, it is likely to be expelled and may be seen or felt in the back part of the mouth If the tube has been properly inserted respiration will become easier in a few minutes The operator then cuts one end of the silk thread, passes his finger behind the epiglottis, and holds the tube while the thread is withdrawn Subsequently, if the tube be of sufficient size, the child may be expected to breathe easily, unless there be extension of the disease

There is little probability that the tube will become stopped by the secretions, but if the breathing again becomes obstructed the tube must be removed and examined Unfortunately, the tube is sometimes expelled by violent cough, and in cases which the physician cannot closely watch lives may be lost by this method which could have been saved by tracheotomy

The tube may remain in the larynx as long as necessary to secure perfect respiration, as it causes little if any irritation There are few cases of membranous croup in which the glottis will be free in less than four or five days, and it is not uncommon for the obstruction to remain ten or twelve days Therefore, if no unfavorable symptoms arise, I would advise that the tube be left four or five days before removal, then if dyspnœa supervenes, it must be re introduced, and it may have to remain ten or twelve days No anæsthetic will be needed for the introduction of the tube, but one will occasionally be required for its removal

Looking at the intubation of the glottis from our present standpoint, it seems well adapted for the following cases

1 For diphtheritic and croupous stenosis of the larynx occurring in children under 3½ years of age
2 For cases of these same affections in older children in which from any cause the physician wishes to defer the operation of tracheotomy
3 For those cases in which consent to tracheotomy cannot be obtained
4 For those cases in which proper nursing could not be secured
5 For severe cases of spasmodic croup in children less than 10 years of age
6 For simple stenosis of the larynx not diphtheritic, in children
7 With proper sized tubes it might be of value in the treatment of various forms of laryngeal stenosis in adults

I have no hesitation in saying that Dr O'Dwyer's instruments for this operation are far preferable to any of the numerous instruments for rapid tracheotomy I can see no good reason why the tubes for older children may not be made much larger than they now are, and if this be practicable the greatest objection to this operation will be removed; however, there will be cases in which the tube may be coughed out, and in which, if the physician leaves the patient, the child may strangle before he can be found to return the tube In such cases the physician would sometimes be culpable for not having done tracheotomy, and thus insured an opening for respiration

The ease with which this method can be carried out will doubtless secure its adoption in a large number of cases in which tracheotomy would not be advised, and thus it may be the direct cause of saving many lives On the other hand, we must not forget that these very features are a source of danger, leading the physician to rely on this method in cases in which nothing less than tracheotomy could be of any avail, and thus many lives may be lost I believe, however, that the method will do much more good than harm, and that within a few years it will find its proper place among the agencies for relieving suffering and prolonging human life Even now I have such confidence in the operation that I think every community should have a set of these or similar instruments in the hands of some physician who has the good judgment to know when to use it

64 State St , Chicago, January 27, 1886

HABITUAL CONSTIPATION IN WOMEN—ITS CAUSES AND EFFECTS[1]

BY H J HARRIMAN, A M , M D ,

OF REVERE MASS

One of the most frequent and obstinate troubles that the general practitioner is called upon to treat is habitual constipation Even the large number of cases that are thus brought into notice are but a small part of those suffering from this cause, since a strange and unconquerable indifference to such a state keeps away all except those who are compelled to seek advice on account of other trouble, possibly the result of this state of the lower bowel So frequently is this state associated with pelvic trouble, that the question naturally arises as to what relation habitual constipation has to the diseases peculiar to women To inquire into this relation and excite discussion on this practical question is the object of this paper With constipation, considered as a symptom, the medical profession are fully acquainted, but of constipation as a disease *per se*, which may be the predisposing if not the exciting cause of more serious trouble, they are inclined to be skeptical

Is this state a *cause*, an *effect*, or simply an *accompanying circumstance* of pelvic trouble? It seems to the writer that its relation is that of a cause, and it will be so treated The physiological functions of the body are wonderfully interdependent Not one can fail to act in its normal way without influencing, either directly or indirectly, the action of every other This influence may be exerted through the general system, through a reflex nervous influence, or mechanically In the case of failure to empty the lower bowel with normal frequency, we find the pernicious influences of such a state exerted in each of these three ways

Of the constitutional effects of such a state malnutrition and spanæmia are generally prominent This is readily understood when we consider the function, or rather the perversion of function of the lower bowel The colon, especially the sigmoid flexure, is intended to act as a depot for the retention of fæces until it is convenient that they be discharged Normally its absorbing power is limited Its excretion consists of mucus and some odoriferous elements of the fæces When, however, the excrement is retained for days, and it may be for weeks, the functions of this organ are so perverted as to give rise to pathological processes The fluid elements are absorbed into the circulation to be excreted by the other emunctories of the body, noxious gases are generated and reabsorbed, and there is created what might be called a vicious circle by the excretion and reabsorption of these noxious elements An idea of the extent to which absorption goes on can be gained by comparing the bulk of fæces when a daily evacuation is gained, and the bulk when the bowels move but once or twice a week In the latter case the amount is not greater than in the former

The effects of such a state can be seen in the slow toxæmia which exerts a benumbing influence on the nervous system and depresses every function in the body Many of the low, nervous manifestations which are usually characterized as reflex are due to this poisoned state of the blood The strength fails, the appetite diminishes and the tongue is foul, there is more or less constant headache, a want of mental power, a constant drowsiness unrelieved by sleep, and fatigue upon the slightest exertion Sleep is not refreshing but is disturbed by dreams and nightmares The extremities are cold Hypochondria and mental depression are common

This state of the general health opens wide the door to all local troubles in the active organs of generation The muscles and ligaments lose their tone and yield readily to such injurious influences as tight lacing, heavy clothing, and indiscretions at menstrual periods The circulation is slow and imperfect owing to the defective performance of the functions of the heart and lungs, and ovulation and menstruation, which nature intended should be painless processes, become sources of anxiety and distress Nearly all writers on diseases of women agree that flexions and versions of the uterus may be due, in part at least, to habitual constipation In anterior displacements the primary influence of fæcal accumulation may be mechanical, whereby the uterus is forced forward upon the bladder, giving rise to troublesome bladder symptoms In posterior displacements and prolapsus the mechanical influence is of minor importance, but the evil is chiefly due to pressure from muscular action while straining at stool

Thomas says "Fæcal impaction may possibly produce flexion of the body and frequently causes the cervix to bend sharply forward " Speaking of cervical flexion he says "It is generally produced by pressure directly exerted upon the uterus by tight clothing, which forces it against the concave surface of the vagina This surface gives the impinging part a slant forward and keeps it thus bent Habitual constipation increases this vicious curve, and the two causes combined often result in an unmanageable form of the affection "

Fæcal impaction may cause, or at least aggravate, menorrhagia and metrorrhagia by interfering with the portal circulation and producing congestion of the pelvic viscera. The author last quoted says: "My experience has furnished me with a number of cases in which fæcal impaction produced prolonged metrorrhagia which was cured by its removal."

---

[1] Read before the Gynecological Society of Boston November 22 1885

Leucorrhœa may be due to the same cause acting in the manner just stated.

It is no easy matter to discriminate closely between the nervous symptoms due to the constitutional influences of such a state, and those due simply to reflex influences. Vaso motor disturbances are very frequent. Variations of temperature have also been noticed. Gastralgia, ovarian neuralgia together with various hysterical manifestations, are often the result of a loaded colon and cured by its relief.

Some of the pernicious influences of habitual constipation seem to be due to a mechanical influence simply, as has already been stated. When the sigmoid flexure and rectum are loaded and distended the uterus is crowded forwards and dysuria results. The soft and pliable uterus of girlhood may be forced into abnormal positions and forms necessitating surgical interference. In rare cases the transverse colon has become so loaded as to be dragged from its attachments. It then descends toward the pelvis and thus increases the pressure on the organs of generation.

The causes of this unfortunate condition are not far to seek. The most of them are so well known as to render their repetition unnecessary. John Burne, writing in 1840, said that constipation was due more to indifference to the act of defecation than to any other cause. The experience of the profession to day will, I think, verify this opinion. This cause, together with false modesty, indolent habits, vicious styles of dress and ignorance of hygiene are fully appreciated by medical men. There are, however, in addition to these, certain causes arising from the anatomical structure and physiological functions of women which render them peculiarly liable to troubles of this nature. At every menstrual period the uterus and ovaries are enlarged and tender, and press, to a greater or lesser extent, upon the rectum. The act of defecation produces pressure upon these sensitive organs and renders the act a painful one, and thus leads to neglect of this function. It is said that constipation is more prevalent in this country than in England on account of the fact that our comparatively dry climate favors the removal of the fluids of the body by evaporation, and thus diminishes the volume of excrementitious matter. However this may be, we know that a withdrawal of the fluid elements of the blood tends to foster if not to produce this condition. This is shown by the influence which lactation exerts whereby defecation is diminished in frequency.

The influences of frequently recurring pregnancies are unfortunate. During gestation the uterus presses upon the colon and sigmoid flexure and interferes with their normal action. The extreme stretching of the abdominal muscles weakens them, and thus renders almost useless these important auxiliaries in emptying the lower bowel. In some cases where many children are borne, the abdominal muscles may become so relaxed that the impregnated uterus may form a pendulous mass in front of the *os pubis*. The great pressure to which the rectum and colon are subjected during labor exerts a paralyzing influence upon the muscle of the bowel. In addition to this, the relaxed state of the pelvic viscera following labor offers a diminished resistance to the great distension of the lower bowel which is so often discovered in cases of long standing constipation.

The nervous state at the climacteric, with its fugitive abdominal pains, and state of apprehension, causes women to dread and avoid any act which may seem to increase their distress. This leads them to neglect entirely or to slight the function of defecation.

Such are some of the causes and effects of this common trouble. It has seemed to the writer that in these days when local treatment of the uterus, both medical and surgical, is so popular, the attention of the profession might with advantage be directed to this state, and that more careful attention to the condition of the *primæ viæ* and general health would render the success of local treatment more certain and satisfactory.

MEDICAL PROGRESS.

The Treatment of Congenital Syphilis by the Older and Newer Methods.—Professor Monti, of Vienna, contributes a valuable paper on this subject to the *Archiv für Kinderheilkunde*, Band vi., Heft 1. Of treatment by inunction, the oldest is that in which blue ointment is employed. It is still largely used; but the objection to it is that it oxidizes too readily in this form, and is then apt to produce eczema. Oleate of mercury is extensively used instead of the blue ointment; and mercurial plasters have been substituted by some, while Charcot, recommends mercurial soap. All those compounds are, however, more or less unsuited to the tender skin of infants, the least objectionable being the oleate of mercury. Dr Monti has, however, had no personal experience of the soap. Moreover inunction involves considerable risk of the system rapidly absorbing an excessive quantity of the drug, and in the case of very young infants this leads to acute anæmia. He has also come to the conclusion that the sudden death, which is not an uncommon incident in hereditary syphilis, occurs with far greater frequency where this has been treated by inunction. For these reasons, he has for some years ceased to use it in the case of children under one year. The next treatment under review is that by calomel. This also has a tendency to produce anæmia, and should, therefore, be given as a powder in combination with lactate of iron. This should be discontinued when the first symptoms have disappeared, and saccharated iodide of iron substituted until the spleen is no longer felt or the skin has resumed its normal color; but should the disease reappear in the skin, mucous membrane, or bones, calomel must again be resorted to. In some rare cases, such as those where there is great irritability of the intestinal tract, a subcutaneous injection of a freshly prepared mixture of calomel suspended in mucilage may be administered.

The treatment by corrosive sublimate gives very satisfactory results, provided it be not to long continued, in which case symptoms of gastric irritation will supervene This drug is also administered in the form of a bath, which should contain about seven grains, but in the writer's experience, their effect upon the disease is very slow, and should therefore be accompanied by calomel internally and in that way they appear to hasten the cure The best mode of giving corrosive sublimate is by subcutaneous injection The solution should consist of perchloride of mercury gr jss, chlorate of soda gr vj, and water 150 grains, and of this one half to one syringeful should be used every day or every other day until the symptoms disappear, to be renewed upon their return The punctures are best made upon the abdomen or chest, and must not be too close together

The injection is in general well borne, and, according to Dr Monti's experience, never produces mercurialism, and causes very little loss of flesh It cannot be denied, however, that infants do not bear these injections so well as adults, even with the greatest care, it is not uncommon to find induration of the cellular tissue and abscesses at the seats of puncture It is also not suitable for out patients, because the mothers decline to bring the children after the first few times Notwithstanding that the symptoms subside more rapidly under this treatment than under any other, the author has of late confined its use to cases that would not bear mercury internally

Albuminate of mercury, as recommended by Bamberger, is preferable for hypodermic use to corrosive sublimate, provided the solution be clear, but it is excessively unstable, and, if used in a cloudy state, produces irritation and abscesses Much the same objection applies to mercury peptone, though it is rather more stable Formamide of mercury (Liebreich) is unsuited to children Protiodide of mercury produces excellent results, especially when combined in a powder with lactate of iron, and perhaps no other remedy acts so promptly upon syphilitic affections of the bones Unfortunately, it produces diarrhœa and colic, and the addition of Dover's powder to the above compound soon ceases to have any effect Consequently, Dr Monti only gives it in cases where bone-affections exist from the beginning Black oxide of mercury, as recommended by Henoch, was found to produce vomiting, and was therefore soon given up The author has had only a limited experience of hydrargyrum tannicum oxydulatum (Ludwig), but is favorably impressed by it, more especially because it does not appear to affect the digestive organs It is now a recognised fact, that hereditary syphilis can be cured by preparations of iodine as well as, though more slowly than, by mercury It may be given as iodide of potassium, to which, however, there are on the whole insuperable objections, or as saccharated iodide of iron The treatment of syphilis with this drug was favorably commented upon by the author in a paper on the subject in 1876, and his subsequent experience of it has confirmed this predilection It is borne well by children of any age, improves their nutrition, and never produces iodism, but it is much slower in its action than mercury, and is therefore best suited for very chronic cases It should be given as a powder, for, if the syrup be used, it is apt to produce diarrhœa Three grains may be divided into ten powders, and a new-born child may have two or three daily, dissolved in milk —*London Medical Record*, January 15, 1886

THE TREATMENT OF PROFUSE HÆMOPTYSIS —In an article on this subject, read before the Medical Society of London, DR SAMUEL WEST gives the following summary of the principles of treatment

1 *Rest* (*a*) of body generally, (*b*) of part diseased Many of the indications under this heading will be met by the use of opium

2 *Hæmostatics* —(1) The topical astringents, (2) the vascular constringents Topical astringents cannot be applied to the bleeding part of the lung, and if they act at all, it must only be as vascular constringents

The belief as to the use of the vascular constringents in pulmonary hæmorrhage is probably based upon an incorrect theory of the pathology, and reasons have been given why they can be expected to do but little, if any, good Ergot was probably introduced on account of its efficiency in controlling uterine hæmorrhage, but it is shown that the necessary conditions for its action do not exist in the lungs unless their action be by vascular constriction, and this is probably ineffectual

As the risk of death in profuse hæmoptysis is not so much from loss of blood as from suffocation, and as profuse hæmorrhage tends to bring about of itself the conditions most favorable to its cessation, an attempt may be made to imitate these conditions in treatment When a vessel is divided hæmorrhage ceases (1) from contraction of the vessel, (2) from clotting of the blood, aided by the great fall in blood pressure which severe hæmorrhage induces

1 *Contraction of the Bleeding-Vessel* —The vessel is so diseased in hæmoptysis, that its muscular coat can no longer act at the diseased spot, and therefore this condition cannot be fulfilled

2 *Clotting of the Blood* —There is, so far as I am aware, no drug which, by internal administration, can increase the clothing power of the blood

The effect upon the blood pressure can be imitated in various ways

1 By free blood-letting from artery or vein This old-fashioned method of treatment is as rational in cases of suffocative hæmoptysis as in apoplexy, for in both cases the risk to life is not from the loss of blood, but from the mechanical effects of the hæmoptysis upon the organ involved

2 If blood-letting be inapplicable, the same end may be aimed at by detaining the blood in some part of the body other than the part diseased, (*a*) for example, mechanically, as by the use of Junod's boot, or free dry cupping, (*b*) or by dilating some of the great vascular systems of the body, and making them act as temporary reservoirs for the blood, (*a*) the abdominal system (purgation), the cutaneous system, counter-irritation, possibly pilocarpin, or even nitrite of amyl These two drugs dilate the vessels throughout the whole body, and might possibly be of great

service Some objections in theory to their action have been considered

3 The blood pressure may be further influenced through the heart (*a*) by means of the cardiac depressants, of which antimony is the most reliable, (*b*) by the nauseating emetics, though their action upon the heart is probably only a part of a more general action Of the emetics, ipecacuanha was much used by Trousseau

4 Lastly, dieting is of great importance The principle of absolute rest and restricted diet, which is the essence of Tufnell's treatment for aneurism of the thorax and abdomen, is equally applicable and useful in pulmonary hæmoptysis

Instead of giving a long list of drugs, or discussing in detail the various methods of treatment of hæmoptysis, I have endeavored in this paper to ascertain the conditions which have to be fulfilled, and to indicate the essential principles which should guide our choice of remedies I have purposely avoided speaking of my own experience, desiring rather to elicit that of others, and although some, of the lines of treatment are, it is true, open to the objection that they are so far speculations, still it cannot be denied that our present treatment of hæmoptysis is far from satisfactory, and perhaps, from the nature of things, may be doomed to continue so Speculation may, perhaps, suggest lines of treatment which experiment may follow out, and of the value of which observation alone is the true test —*British Medical Journal*, January 16, 1886

New Procedure for the Removal of Small Calculi from the Bladder —Mr Thomas Annandale reports the following case in which he adopted a new procedure for removing small vesical calculi from male children A boy, aged 4¼, was sent to me on account of symptoms of stone in the bladder which had existed for about a year The usual symptoms were present and well marked, and, upon sounding him, I detected a small and light stone

On December 10, I put him under the influence of chloroform, and dilated urethra by passing Nos 6, 7, 8 and 9 silver catheters in succession The first three passed readily, but No 9 was slightly grasped in its passage along the urethra Before removing this last catheter, four ounces of antiseptic fluid (corrosive sublimate 1 to 4,000) were injected through it into the bladder This catheter being withdrawn, a small lithotrite, having a diameter about equal to a No 8 bougie, was introduced along the urethra into the bladder After a little careful manipulation, the stone was seized, and fixed between the blades of the instrument It was then found that, by depressing the handle of the lithotrite, its vesical extremity, together with the stone, could be readily felt through the abdominal wall immediately above the pubes The lithotrite being held in this position, a small incision, an inch in length, was made in the middle line of the abdominal wall over the pubes, and for a short distance above it The various tissues were divided, until the wall of the bladder was exposed at the point against which the blades of the lithotrite and the enclosed stone were pressing A little further depression of the handle of the lithotrite caused the extremity of its blades covered by the stretched wall of the bladder to protrude through the wound in the abdominal wall, and a small incision having been made through the wall of the bladder by cutting upon the extremity of the lithotrite, the blades of the lithotrite, together with the stone, were pushed through the wound The stone was here extracted from between the blades of the lithotrite, and the open extremity of a No 7 India rubber catheter was seized, and drawn into the bladder and along the urethra as the lithotrite was removed, thus leaving a drain for the urine to escape from the bladder The wound in the abdominal wall was closed by means of two horse-hair stitches, and a drainage tube introduced into it so as to aid the escape of any urine which might flow from the bladder wound Irrigation with corrosive sublimate solution (1 to 2,000) was employed during the operation, and the wound and parts around were covered with a dressing of corrosive sublimate wool The stone removed was about the size of horse bean, of uric acid formation For the first thirty six hours after the operation, the urine was slightly tinged with blood, passed principally by the abdominal wound, but after this, it flowed through the catheter, which had been secured in the bladder

Forty eight hours after the operation both drainage-tube and catheter were removed, the patient not having had the slightest bad symptoms For twelve hours after the removal of the drainage-tube and catheter, the urine came by the abdominal wound, but, after this, it passed almost entirely by the urethra, and the patient was running about the ward, perfectly well, on the tenth day after the operation

It may be said that this is simply a suprapubic lithotomy, and so it is, but I maintain that it is a much less serious proceeding than the ordinary suprapubic operation, as the bladder is scarcely disturbed, and the wound made in it is very limited Its advantages over lateral lithotomy are 1 That the urethra, prostate, and neck of the bladder are left uninjured, 2 That it is a much more simple proceeding, and does away with the principal risks which have occasionally been encountered in performing the operation on children

I confess that it requires a little manipulative dexterity to seize a small stone in a male child's bladder, but no greater dexterity is required in doing so than what every surgeon, professing to be an operating surgeon should possess

It is possible that in certain cases the same principle might be carried out, by bringing the stone to the neck of the bladder, opening the prostatic part of the urethra, and thrusting the blades of the lithotrite and contained stone into the perineal wound, but in the case of children there can, I think, be no doubt that the suprapubic method is preferable —*British Medical Journal*, January 2, 1886

New Operation for the Alleviation of Persistent Deafness —Dr William H Bates, of New York, in an article on this subject says that many cases of deafness are not benefited by thorough catarrhal treatment, inflation of the middle ear, the use of Siegle's otoscope, an artificial opening in the drum membrane, division of the tensor tympani, etc He calls attention to an operation which has benefited a number of these obstinate cases The operation consisted in puncturing or incising the drum-membrane in from five to ten different places Simple punctures were made, or the drum membrane was slit in various directions The operation was repeated as soon as the openings in the drum-membrane had healed The size and freedom of the incisions must be determined after the first operation for each case

For the operation he employed a Graefe cataract-knife with a long shank It is important that the knife be *sharp*, and to make this certain he often used a freshly sharpened knife for each puncture Pain was avoided by this precaution A dull knife, or the paracentesis instruments sold in the shops, caused more pain than the patients could bear

Cocaine was not necessary when the knife blade was in proper condition, and this remedy would not prevent pain when the knife was dull

The result of this operation is to leave a number of cicatrices in the drum-membrane, the subsequent contraction of these producing a tension by which the membrane is drawn out The membrane frees itself from adhesions in this manner, and in many cases loosens the anchylosed ossicles The various benefits of paracentesis, as formerly employed, are not only obtained but much increased It is not an improvement the result of a perforation of the drum membrane alone which, as is well known, is often doubtful and transitory, but the subsequent healing of the openings is part of an improving process The operation, suggested by that of paracentesis, differs from it in the simultaneous number and extent of the incisions, as well as in the purpose for which it is resorted to, and in the immediate and subsequent results —*New York Medical Record*, January 23, 1886

THE INFLUENCE OF ALCOHOL AND OF MORPHINE ON PHYSIOLOGICAL OXIDATION has been studied by Sumanowsky and Schoumoff Adopting Sieber and Nencki's suggestion, the oxidation of ingested benzol to phenol was taken as a measure of the systemic oxidation The elimination of phenol lasts from two to four days In the case of a dog which normally excreted 0 283 to 0 248 gramme of phenol for every gramme of benzol ingested, the administration of 0 3 gramme of alcohol per kilogramme of body weight reduced to the elimination to 0 165 gramme, while an increase in the alcohol to 3 01 grammes per kilogramme reduced the phenol eliminated to 0 125 gramme On the other hand, the administration of 0 02 gramme of morphine hydrochlorate per kilogramme increased the phenol to 0 309 gramme In a man, aged 27, two grammes of alcohol per kilogramme of body-weight reduced the elimination of phenol, after the ingestion of two grammes of benzol, from 0 82 to 0 33 gramme The morphine therefore seems to increase the oxidizing powers of the system, while alcohol correspondingly decreases them The quantity of urea excreted appears also to be diminished by alcohol, although the excretion of urea cannot be taken as a measure of organic oxidation Diminished oxidation, produced by constriction of the air-passages, which increases the elimination of urea, lessens the amount of benzol oxidized to phenol in the system In none of these cases, it may be said, could more than traces of the alcohol ingested be discovered in the urine —*London Medical Record*, January 15, 1886

THE PREVENTION OF MYOPIA IN SCHOOL CHILDREN —It is now tolerably well established that shortsightedness is developed and increased in a certain direct relation to the amount of school-work done by children For the prevention of myopia, Fuchs, of Liège, in a prize essay, quoted in the *Birmingham Medical Review*, gives the following directions First in importance is the arrangement and lighting of the schoolroom

"The principal windows in England should look to the south or south east The long axis of the room should run north and south Every scholar should, from his place, be able to see some portion of the sky Light from above is the best, and, except in hot climates, glass roofs are very advantageous The chief light must come from the scholar's left side The height of the top of the window from the floor should not be less than two thirds the width of the room The total window surface should bear to the area of the floor a proportion of at least 1 to 5 In artificial lighting by gas, every burner must have a glass chimney and a shade, the latter arranged to reflect the light down upon the desk, and to screen the scholar's eyes There should be about one burner to every four scholars "

It is most important that the eyes should not be approximated too closely to the book The proper position is that in which the shoulders and pelvis are parallel with the edge of the desk, and the head upright or bent but slightly forward As to the construction of desks and seats, there must be several sizes, to suit scholars of various ages, the distance between seat and desk, in the vertical direction, must be but little greater than the distance between the elbow and the ischial tuberosity The edge of the desk must overhang the seat about two inches, the scholar can then sit upright The surface of the desk must slope about 1 in 5, to obviate the bending forward of the head, and the breadth should not be less than 15½ to 16 inches All stooping should be avoided, and the types used must be perfectly legible —*British Medical Journal*, January 16, 1886

SPARTEINE IN HEART DISEASE —PROF GERMAIN SEE has recently subjected Laborde's deductions from experiments to the test of clinical trials, the patients being two persons with degeneration of the cardiac muscle, one with mitral stenosis, one with mitral insufficiency, one with aortic stenosis, and one with cardiac asthma and albuminuria From the action of the drug in these cases he concludes that sparteine sustains the action of the heart, improves its rhythm, and accelerates its movements —*N Y Med Journ*, January 2, 1886

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE	$5.00
SINGLE COPIES	10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

SATURDAY, FEBRUARY 6, 1886.

THE DIVISION IN THE PROFESSION OF NEW YORK STATE ON CODES OF ETHICS—ITS BEARING ON THE INTERNATIONAL CONGRESS DIFFICULTY.

It has been asserted that much of the trouble with regard to the organization of the International Medical Congress has been due to dissensions, which have existed and which now exist in the profession in the State of New York, and it is assumed by some that these dissensions are little more than a local quarrel, having no proper relation to the profession at large or to the proposed organization of the Congress. Although the profession of the State of New York is certainly divided in opinion on the question of medical ethics, the quarrel—if one have existed—has long since disappeared from public view. That there actually is a division of the profession in New York is shown by the existence of two distinct State medical organizations. The Medical Society of the State of New York, organized by act of Legislature in 1806, in its volume of "Transactions" for 1884 showed a total active membership of 392. In 1882, this Society repealed the Code of Ethics of the American Medical Association. In 1884 the New York State Medical Association was founded as a voluntary organization. In its volume of Transactions for 1884, the Association showed a total active membership of 514. This Association adopted the Code of Ethics of the American Medical Association as a fundamental part of its organization.

Inasmuch as the condition of the profession in the State of New York is supposed by some to have a bearing upon the organization of the International Medical Congress, it is of interest to the profession at large to know, if possible, the exact status of the two parties into which the regular profession is said to be divided. The New York State Medical Association is in affiliation with the American Medical Association, and with the regular profession of the United States. The Medical Society of the State of New York is no longer in affiliation with the American Medical Association, for the reason that it does not accept the Code of Ethics of the Association. So far as the so called division of the profession in the State of New York is concerned, we shall give to our readers the facts as they appear in publications readily accessible, with no expression of opinion upon the questions involved. If these facts have any proper relation to the organization of the International Medical Congress, this will appear without argument; and certainly the profession of this country and of other countries should be made acquainted, as nearly as possible, with the exact condition of the profession with regard to medical ethics.

The provision of the Code of Ethics of the American Medical Association, which constituted the main subject of discussion in New York, refers to consultations and is embodied in the following:

"But no one can be considered as a regular practitioner or as a fit associate in consultation, whose practice is based on an exclusive dogma to the rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry."

In 1882, by the two thirds vote required, the Medical Society of the State of New York repealed the Code containing this provision, and adopted the so called "New Code," which has the following provision with regard to consultation:

"Members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine." (The phrase "legally qualified practitioners of medicine" introduced here we will continue to use throughout this article, although there is no law in this country establishing a *legal standard* of *qualifications for practitioners* of *medicine* in the same sense as in the countries of Europe. With very few exceptions, our laws regulating the practice of medicine are practically simply registration laws, requiring all sorts of practitioners, *regular* and *irregular*, to register their credentials in the clerk's office of the county in which they practice and obtain a license which gives them authority to practice, without furnishing any proof that they have either adequate scientific or professional attainments for the practice of medicine.) The "New Code" was adopted in the Medical Society of the State of New York by a vote of 52 to 18, 70 members being present and voting. In 1884, an effort to repeal the "New Code" and to reestablish the Code of the American Medical Association was defeated by a vote of 123 to 105, 228 members being present and voting.

The exact status of "legally qualified practitioners of medicine" with whom "members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith" are now permitted to consult, and with whom many so called regular physicians in the State of New York do now freely consult, was fixed in 1880, nearly two years before the adoption of the "New Code,' by an act of Legislature entitled "An Act to Regulate the Licensing of Physicians and Surgeons." It may be assumed that those who advocated the adoption of the "New Code" were aware of the character of certain practitioners with whom consultations were permitted under the "New Code," inasmuch as certain of the advocates of the "New Code" were active in preparing the bill under which practitioners are now registered in the State of New York. In 1883, Messrs. Caswell, Hazard & Co., druggists, of New York City, printed and distributed a list of "Registered Physicians in the County of New York, compiled and alphabetically arranged from the official list in the office of the County Clerk, to January 14, 1881, revised to January 1, 1883." This list, with the report of the Illinois State Board of Health on "Medical Education and Medical Colleges in the United States and Canada, 1765–1885," giving the standing of the medical colleges of the United States, and the "Medical Register of New York, New Jersey and Connecticut," for 1883–84, has been used in the following analysis. The "Medical Register" is supposed to contain the names of all legally qualified regular physicians in the County of New York. The number of such physicians in the "Register" of 1883–4 was 1,661. The register in the office of the county clerk contains not only the names of the regular physicians who are named in the "Medical Register," but the names of all "legally qualified practitioners of medicine."

An analysis of the county clerk's register shows the following: 388 irregular practitioners are registered. Of this number, 38 are graduates of regular medical colleges, but are members of the "Homœopathic Society of the County of New York," while 350 are graduates of irregular medical colleges. The following colleges are the irregular institutions named in the register. Notes of the status of each college, where this is not plainly indicated by the title of the institution, are copied from the report of the Illinois State Board of Health on the medical colleges in the United States, 1765–1885.

1. Eclectic Medical College, New York. 2. Syracuse Medical College (Eclectic). "Organized 1849, extinct, 1855." 3. United States Medical College, New York (Eclectic). "Organized in 1878, in a manner that has since been declared illegal by the State Supreme Court. Extinct since 1882." 4. Philadelphia University of Medicine and Surgery (Eclectic). "Incorporated in 1859. Fraudulent. The sale of diplomas was stopped by legal process, and the arrest of Miller and others in 1880." 5. Eclectic Medical College, Cincinnati, Ohio. 6. Bennett College of Eclectic Medicine and Surgery, Chicago, Illinois. 7. New York Medical College for Women (Homœopathic). 8. Homœopathic Medical College, New York. 9. Hahnemann Medical College, Philadelphia, Pennsylvania. 10. Worthington Medical College, Ohio, afterward the Eclectic Medical Institute. 11. Metropolitan Medical College, New York (Eclectic). "Organized in 1852, incorporated March, 1857. Charter repealed April 12, 1862." 12. Hygieo Therapeutic College, New York. "Extinct." 13. Homœopathic Medical College, Cleveland, Ohio, and Western Homœopathic Medical College, afterward consolidated under the name of the Homœopathic Hospital College. 14. Eclectic Medical College of Pennsylvania. 15. Electro Therapeutic Institute of Philadelphia. 16. St. Louis Eclectic Medical College. "Organized in 1874—extinct in 1883. Closed by legal process." 17. Hahnemann Medical College, St. Louis, Missouri. 18. Massachusetts Medical College. No information. 19. Homœopathic Medical College, Leipsic. No information. 20. Physio-Medical College, Cincinnati, Ohio. "Organized in 1836, graduated classes until 1880. Extinct." 21. American Institute of Phrenology. No information. 22. Germantown Medical College, District of Columbia. No information. 23. Hudson University, Cleveland, Ohio. No information. 24. Mexican Homœopathic Institute. No information. 25. Ohio Botanic Medical College. No information. 26. New England Female Medical College, Boston, Massachusetts (Homœopathic). 27. Penn University, Philadelphia, Pennsylvania. "Fraudulent. Extinct." 28. New York State Homœopathic Medical College. No information. 29. American University of Philadelphia. "Incorporated in 1867. Fraudulent. Extinct. The sale of diplomas was stopped by legal process, and the arrest of Buchanan in 1880." 30. American Medical College of St. Louis (Eclectic).

31 Pulte Medical College, Cincinnati, Ohio (Homœopathic) 32 New York Ophthalmic Medical College No information 33 License by Professor Pfeiffer No information

If it be assumed that the profession of the State of New York is divided into two classes, these classes may properly be defined—at least so far as can be judged from what has been published regarding the troubles in New York—as one, composed of members of the Medical Society of the State of New York, and others, who sympathize with the so called New Code of Ethics, and the second, composed of Fellows of the New York State Medical Association, and others, who adhere to the Code of Ethics of the American Medical Association The "New Code" party admits the propriety of professional recognition of and of free consultation with the 388 practitioners, legally qualified to practice, but generally regarded as irregular, registered according to law, and with irregular practitioners registered in other counties The "National Code" party refuses professional recognition of and consultation with any but regular physicians in good standing

The questions which have divided the profession of New York—which seem to be not without interest and importance to the profession at large—were brought indirectly before the meeting of the American Medical Association in 1885, following the publication of the rules and preliminary organization of the Ninth International Medical Congress, by what is known as the Original Enlarged Committee of the Association This committee appointed 56 physicians from New York as officers of the Congress and of the Sections Of this number, 27 were on record as adhering to the "National Code," 20, as having adopted the "New Code," and the remaining 9, either as in favor of no code of ethics or as uncommitted or unclassified This classification is taken from a publication issued by a body of physicians in New York City, which afterward organized the New York State Medical Association The American Medical Association decided that the Original Committee appointed in 1884 exceeded its powers in appointing the officers of the Congress, and, at its meeting in 1885, the Association enlarged the Original Committee by adding members representing different sections of the United States, and instructed the Committee, thus enlarged, to "review, alter, and amend" the work of the Original Enlarged Committee, and to appoint the officers of the Congress

The New Committee held several meetings, made a preliminary organization of the Congress, and entrusted the details of the further organization to an Executive Committee composed of the titular officers of the Congress and the Presidents of Sections, with power to increase its membership to a total number not to exceed thirty The Committee on Organization having thus completed its necessary work, put the affairs of the Congress absolutely in the hands of this Executive Committee, which Committee is now perfecting the organization of the Congress in accordance with the rules adopted by the Committee of the American Medical Association

The rules of the Congress admit as members all regular physicians without restrictions as regards opinions on the question of medical ethics, but the Committee virtually acted in accordance with what appeared to be the sense of the body by which it was appointed, which was "that it should place no man in any official position who is in direct opposition to the Code of Ethics of the American Medical Asssociation'" and of all the affiliated State Medical Societies in the United States The present status of the organization of the Congress is that the so-called New Code representatives from New York are freely eligible as members of the Congress The demand of certain members of the profession, who have declined to take any part in the Congress, seems to be that all the officers appointed by the Original Committee shall be restored, including the "New Code" officers from New York, and that the organization of the Congress shall be put back into its original form

If the question involved be one of principle, that principle is whether or not members of the regular profession who advocate consultations with any and all legally qualified practitioners, including such as are registered in the County of New York from the irregular colleges, shall be recognized by appointment to offices in the Congress If the question relate merely to individuals, it resolves itself into one of the appointment as officers by a Committee originally derived from and appointed by the American Medical Association, of members of the profession who are in direct opposition to its Code of Ethics

The foregoing is a simple statement of what appear to be the relations of the profession of New York to the organization of the next International Medical Congress, giving the condition of medical matters in the State as it appears from printed records and documents, without trending upon the questions of geographical distribution of offices and the proper functions and powers given by the American Medical Association to its Original Committee on Organization of the Congress

"THE MITRAL CARDIAC MURMURS"

Under this title is an admirable contribution by DR. A. FLINT, SR. to the January number of the *American Journal of the Medical Sciences*. As stated by its author, the paper is not designed to add any new facts to what is already known of the subject, but merely to call the attention of the profession anew to some of the characters of heart murmurs belonging to the mitral area. The paper is written in the author's happiest style, and would repay every general practitioner for its perusal.

Mitral murmurs are divided by the author into four classes as follows: Mitral regurgitant, mitral non-regurgitant or intraventricular, mitral presystolic, and mitral diastolic murmurs. A systolic murmur which is heard with greatest intensity at or near the heart's apex is of so common occurrence as to be familiar to almost every physician, and is generally considered to denote incompetence of the mitral valves. In the majority of cases this murmur is propagated to the left and is audible upon the back. It is accompanied, too, with an accentuation of the second pulmonary sound and demonstrable enlargement of the right ventricle. In such a case there could be no reasonable doubt thrown upon the existence of an insufficiency of the bicuspid valves. According to Dr. Flint there may be heard at times a systolic murmur, having its maximum of intensity at or near the apex, which, however, does not depend upon a regurgitation of blood into the auricle. It is produced within the left ventricle, and hence is termed by Flint "intraventricular" or "non regurgitant." He does not attempt to account for its production in all cases, but thinks it might occur if there were a deposit of fibrine upon the ventricular aspect of the valves as the result of endocarditis.

In support of the existence of such a murmur, he cites a case reported by Dr. Janeway, of New York, in which the necropsy showed that the mitral systolic murmur heard *intra vitam* must have depended for its production upon a tendonous band which stretched across the cavity of the ventricle, since the valves were competent. Dr. Andrew H. Smith attributes the murmur in question to the friction of the opposed edges of the valve segments. But this theory Dr. Flint does not consider adequate to its explanation. That a non regurgitant murmur may exist is, according to the author, borne out by the clinical fact that in such cases the secondary and disastrous results of regurgitation never develop. George Balfour, on the contrary, regards such cases as instances of functional, not organic incompetence of the bicuspid valves, depending upon the relaxation of the ventricular walls and consequent stretching of the auriculo-ventricular orifice. With this theory Dr. Flint is by no means in accord. As might be expected, the differential diagnosis of a mitral regurgitant or non-regurgitant murmur is not always easy. But, if Flint's view be correct, that a mitral systolic murmur may exist without incompetence of the valves, there can be no increase of pressure within the pulmonary circuit, and hence no accentuation of the second pulmonary sound. This, it seems to us, ought to prove a valuable aid in determining the true nature of such a murmur. In some cases, the author says, a non-regurgitant may be combined with a regurgitant murmur. It is then to be distinguished by its softness and blowing quality.

Of the presystolic murmur Dr. Flint has much to say. His description of its character corresponds with that of other competent observers, viz., that it is rough and usually loud. He denotes it as "vibratory or blubbering," thereby meaning the same as those who call it "rolling," "grinding," or "churning." As to the mode of its development, however, all observers are not in accord. Flint asserts his belief in its dependence upon that condition of the valves in which the edges are glued together, thus forming a funnel shaped sack with a button hole slit. Hilton Fagge, in "Reynolds's System of Medicine," appears to regard this distortion of the valves as that most often found in cases in which a rough presystolic murmur was heard during life. Douglas Powell has essayed to prove that the most usual form of valve associated with this murmur is what he has termed the "diaphragmatic valve." In this condition the valve is stretched diaphragm like across the ostium, leaving a constricted opening. Balfour adopts this theory of Powell, and plainly states in the present edition of his "Lectures on Diseases of the Heart" that in the majority of cases with a rough presystolic murmur the valves do not present the funnel shape described. It is probably within bounds to state, however, that the majority of observers agree with Flint upon this point.

There is another question pertaining to the presystolic murmur in which the author appears to stand alone. It is as to whether a presystolic murmur may ever be pesent without stenosis of the mitral orifice. Dr. Flint has reported three cases in which he observed such a murmur, yet in which the autopsy revealed no constriction of the *ostium venosum sinistrum*. In two of the cases the valves were healthy, while in the third there were small vegetations upon the auricular aspect of the curtains at their base. In all three cases aortic incompetence existed and had been diagnosticated *intra vitam* from its characteristic murmur. Balfour openly charges the author with inability to recognize a presystolic murmur and with having confounded it with the aortic diastolic one present in all of the cases. To accuse so competent and experienced an observer as Dr. Flint of such ignorance and negligence is discourteous, to say the least, and it is not strange that the author should feel incensed. Whether his explanation of the phenomenon be tenable or not, the correctness of his observation ought not to be doubted.

Lastly, the author directs attention to the not infrequent presence of a mitral murmur which is diastolic. That is, it occurs at or just after the second sound and is separated by an appreciable interval from the succeeding ventricular systole. This is as definitely characteristic of mitral stenosis as a presystolic murmur, and has been observed to develop after the subsidence of the latter. It is somewhat soft and bellows-like in quality. Bramwell attributes its production at the beginning of diastole, to the increased force imparted to the inrushing stream by the aspiration of the relaxed ventricle. The author, however, is not inclined to endorse this explanation. Whether this mitral diastolic murmur can be accounted for satisfactorily or not, the occurrence of such a phenomenon cannot be denied, and in the author's opinion, is entitled to the classification accorded to it, except indirectly. Dr. Flint says nothing concerning another diastolic murmur that is occasionally heard with maximum intensity at the apex, yet is not generated at the mitral orifice. This is that very rare form of aortic regurgitant murmur first described by Balthazar Foster and recognized by both Balfour and Fothergill. In case the posterior segment of the aortic valves be ruptured, the ensuing murmur is said to be loudest at the apex instead of at the middle of the sternum. Foster is said to have made the diagnosis of incompetence of the posterior cusp in one case, in which it was verified by the necropsy. Although this murmur is not mitral in the sense of being generated at the mitral orifice, it is such with respect to the area of its greatest intensity, and hence might mislead an observer not acquainted with the possibility of its occurrrence.

Dr. Flint's paper is succinct and full of matter for reflection. Among other things the thought is suggested by the wide divergence of authors concerning the mode of production of certain murmurs, that perhaps all of them may be right. If Savart's theory be correct, viz. that intracardiac as well as intravascular murmurs are caused by the audible vibrations of fluid veins, there is reason to suppose that a variety of conditions may produce these sonorous fluid veins. Accordingly, in the first case reported by Dr. Flint, the vegetations upon the auricular surface of the mitral curtains may have generated such fluid veins, even without stenosis. Similarly, in the other cases, conditions dependent upon some peculiarity in the stream regurgitating from the aorta may have produced fluid veins at the very instant of the auricular systole, and thus given rise to a presystolic murmur. Also, may not a variety of conditions produce non-regurgitant or intraventricular murmurs? Moreover is it wise to attempt to explain all murmurs occurring in the pulmonary area as the result of one and the same physical condition? May not Naunyn's theory, which Balfour defends, be true of some cases, while in others the murmur is hæmic and located in the pulmonary artery?

Much as we flatter ourselves we know of the physical diagnosis and of the pathological conditions of the heart, we are yet wofully ignorant of many things which more extended clinical observation, supported by post mortem examinations, will probably reveal to the ken of future generations.

FELSENREICH'S MODIFICATION OF ALEXANDER SIMPSON'S AXIS TRACTION FORCEPS.

We desire to call attention to Dr. T. Felsenreich's paper, entitled "Experiences with the Axis-Traction Forceps," appearing in another column, for two reasons: 1. It is a valuable contribution to the literature of the subject of the axis traction forceps by an accomplished obstetrician of very large experience; 2. It settles conclusively a question, in regard to which some difference of opinion seems to exist. Dr. L. E. Neale of Baltimore, presented to the Medico-Chirurgical Faculty of Maryland, in Baltimore, and the American Gynæcological Society, in Washington, 1885, a model of an axis traction forceps, which he has since decribed under the title, "An Obstetric Forceps," in the *American Journal of Obstetrics*, September, 1885.

It was asserted in our editorial columns, September 26, 1885, that the instrument as described by Dr. Neale in the journal mentioned, was identical in all essential details with Felsenreich's modification of Alexander Simpson's axis-traction forceps; that this valuable instrument (Felsenreich's modification of Alexander Simpson's axis traction forceps) was used in Braun's clinic, exhibited in courses on operative obstetrics, and exposed for sale by Mr. J. Leiter during Dr. Neale's sojourn in Vienna, a considerable period of time prior to the construction of the so called Neale axis traction forceps, that Felsenreich's modification could scarcely have escaped the observation of such an acute, zealous, and industrious student as Dr Neale, and, finally, that Dr Neale's allusion to Dr Felsenreich[1] in the paper mentioned, was disingenuous

Some correspondence ensued between Dr Neal and the editor of THE JOURNAL, which resulted in a communication to Dr Felsenreich, now Docent in obstetrics and gynæcology at the University of Vienna Dr Felsenreich's reply is published without comment, as the point in question is discussed in no unequivocal terms

SOCIETY PROCEEDINGS

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, January 13, 1886

THE PRESIDENT, C H A KLEINSCHMIDT, M D, IN THE CHAIR

T E McARDLE, M D, SECRETARY

DR BERMANN presented a number of

NASAL POLYPI

removed from one person These tumors, he said, were not gelatinous, but fibrous, and showed under the microscope a large number of connective tissue corpuscles The patient was supposed to have had bronchial catarrh She suffered from asthmatic attacks and was unable to breathe through the nose Her general health was much affected and she presented quite a decrepit appearance when first she came to his office He removed the polypi with a snare, taking away as many as he could see at each sitting He cauterized the points of insertion with tri chlor acetic acid, and believed that the tumors would not return The proceeding was painless At first he used cocaine, but afterwards dispensed with it on account of its numbing influence on the patient's tongue He related the salient points of a similar case which had been under his care in Baltimore

DR J FORD THOMPSON did not understand why Dr Bermann should use a snare when forceps is so much more convenient and simple He himself had removed polypi with forceps which could not be reached with the snare He could thus remove as many as he desired at one visit

DR BERMANN thought the forceps too rough an instrument for such delicate work Moreover, in his experience it was not as satisfactory as the snare, for the forceps could not reach points which could be reached with the latter instrument, for example, the lateral surface of the turbinated bone between it and the antrum

(To be concluded)

Stated Meeting, January 20, 1886

THE PRESIDENT IN THE CHAIR

DR H C YARROW read the history of a case of

PAPILLOMA OF THE BLADDER

The patient, a male, aged about 45, noticed some fourteen years ago an irritability of the bladder, a constant desire to micturate, with scanty flow, and after a time a profuse discharge of bloody urine, subsiding within variable periods of time under the administration of appropriate medicines This condition of affairs continued until the winter of 1884, when he came under Dr Yarrow's care, and he supposed at this time that he was suffering from renal hæmorrhage He was examined very carefully with a view to determine the origin of the bleeding, and all possible sources were excluded with the exception of a surmise that a tumor or villous growth perhaps existed His urine was frequently examined microscopically, but no signs of a growth were discovered All sorts of hæmostatics were employed in addition to local remedies, but the bleeding still continued, until finally it was decided to try and remove a portion of the growth if one was present, by means of a searcher, or short curved sound Sweeping this instrument carefully around the inside walls of the bladder, it met with an obstruction at the lower portion of the posterior wall, but it was impossible to say whether there was a growth or simply a rugous condition of the wall The beak of the instrument was passed over it several times, and then all further manipulation was abandoned There was very free hæmorrhage the next day, and in the afternoon several shreds of tissue were passed, these being submitted to microscopical examination, proved to be portions from a papillomatous growth The diagnosis was submitted to the patient, and he was advised to have the growth removed, but the bleeding ceasing after awhile, he concluded not to have anything done

He had no further return of serious hæmorrhage until November, 1885, when he again placed himself under Dr Yarrow's care He was again advised that an operation should be performed, especially as the diagnosis was confirmed by the examination of another shred from the growth, but he hesitated until grave fears were expressed for his life He was losing daily an appalling amount of blood, and was becoming manifestly weaker day by day, notwithstanding all known remedies were used to control the bleeding He finally agreed to an operation, and for reasons best known to himself preferred to visit Philadelphia and have it performed by Dr D Hayes Agnew At the patient's earnest request Dr Yarrow accompanied him to that city, and on December 16 he was operated upon in the presence of the class The operation was the one proposed by Sir Henry Thompson, called by the old French surgeons the boutonnière, and may be briefly described as follows The patient having had the perineum shaved, and being anæsthetized, the bladder being filled with water, was placed in the the lithotomy position, and a medium staff, short curved and widely and deeply grooved, was passed into the bladder, and was there firmly held hooked up under the pelvis by an assistant The operator, seated, passed the left index finger into the rectum, feeling with its tip the position of the staff and placing the point of the finger on the apex of the prostate as a guide Then with a long, narrow, straight-backed bistoury, a vertical incision was made through the skin and cellular tissue in the line of the raphé, an inch and a quarter long, the lower border terminating three quarters of an inch above the anus The bistoury was entered, cutting edge upwards, horizontally at the lower border of the incision above the bowel, and parallel with it, and the point was directed inwards until it penetrated the membranous portion of the urethra, entering the groove of the staff The urethra was then incised on the staff for a short distance, taking care not to wound the bulb The knife was withdrawn and a gorget like director passed into the groove of the staff and pressed firmly but gently along the urethra into the bladder The staff was then withdrawn and the left index gently insinuated along the director into the bladder, the director was withdrawn, and the right hand was used to make firm supra-pubic pressure, and bring all parts of the bladder within reach

---

[1] 'The idea of its construction is not *entirely* original with me as the button hole joint for the traction rods was first shown to me by Dr Felsenreich, first assistant to Prof Carl Braun of the Vienna clinic in 1882" —The American Journal of Obstetrics September 1885

The growth on the posterior wall was at once found by Dr Agnew, who proceeded to remove it by using one of Thompson's forceps This growth was nearly as large as an English walnut Further exploration revealed, on the anterior wall of the bladder, another and a larger growth, which was also removed, the two masses together being half as large as a man's fist The bladder was washed out with carbolized water some carbolized cotton applied to the wound, and the patient sent to his bed During the operation not over four ounces of blood were lost No untoward symptoms presented themselves at any time while he remained in the hospital, and on December 31st he returned to his home in Washington apparently well, the incision having entirely healed On the third day after the operation urine passed through the urethra without a tinge of blood, and at the present time he seems perfectly well, being no longer troubled with symptoms of vesical distress, which made life a burden to him

Comparing this operation of Thompson's with the suprapubic or with the ordinary lithotomy operation, I think the advantages are all in favor of the former The bladder and its neck are not injured in any way, and, in short, it is one of the simplest and least dangerous of surgical operations In the suprapubic operation it is almost always necessary to make a counter opening in the perineum for drainage, and even if this be done, statistics show that many patients perish of peritonitis If the growth be so large that it will not pass through the vesical neck, it may be removed piecemeal, divided within the bladder, or removed by lithotomy operation, or a suprapubic incision In some cases Dr Thompson uses small saw like instruments like Hey's saws to remove the growth, but in the majority of cases the forceps are sufficient In case of bleeding from the base of the tumor after removal he uses syringes of peculiar form intended to make a direct application of some one of the hæmostatics In Dr Yarrow's case all bleeding stopped so soon as the growths were crushed off With regard to the statistics of the operation, he will give the results of the twenty cases of vesical tumors operated on by Sir Henry Thompson up to the year 1884, in his own words "Of the twenty cases of tumor, two were in women one of these died in three days of total suppression of urine, autopsy showing advanced disease of kidneys (one contained a large calculus), and that no injury was inflicted upon the bladder The other is now in excellent health, having entirely lost her painful symptoms, observing a few drops of blood, occasionally, after more exercise than usual More than two years have elapsed since the operation Of the eighteen male cases, five died within three weeks after the operation, three others at periods of some months after, two of them from malignant disease developed elsewhere The other nine are living, one of these, from whom I removed a tumor in the autumn of 1882, I operated on again, removing a larger growth than the original one last February, and he has again recovered In four cases no attempt was made to remove the tumor, it being manifestly impossible to do so, but only to diminish it as far as practicable with safety, all these recovered well, and are rather better than before Of the remaining four, one has had no return whatever, four years having elapsed since the operation, a second has slight signs of a return, one year and a quarter since operation, but works hard for his living at 64 years of age, a third who, like the last, was at death's door from loss of blood when I operated, has greatly improved, and is actively employed, but has recently shown some disposition to bleed after exercise, nearly a year since operation The fourth was greatly improved, and returned to the active life for which he was before disqualified The others have too recently been operated on to furnish any material fact to be reported More ample details are furnished in the table of cases I may thus briefly sum up the record of the numerous facts related For every one of these patients with tumor, in the natural order of events, one result only was possible Left to themselves, without surgical aid, death inevitably awaited each, a fate not merely certain, but involving protracted suffering"

A portion of the growth removed from the patient whose case has been reported has been examined by Dr Gray, of the Army Medical Museum, and he reports as follows "The enclosed specimen is a section taken from the tumor of bladder removed by Dr Agnew December 16, 1885 It is a fimbriated papilloma, under the microscope it shows a number of single and branched papillæ The core of these papillæ is made up of delicate connective tissue covered with layers of columnar epithelioma, which rests on a delicate basement membrane The growth is usually known as a soft papilloma"

In conclusion, Dr Yarrow said that when we read accounts of certain operations described by the great masters of surgery, in the mere reading they appear very simple, but when we come to put into practice the unusual dexterity needed we occasionally find the work much more difficult than we supposed He does not think such is the case with regard to Thompson's operation Anticipating that his patient would sooner or later consent to an operation, he practiced it upon the cadaver, hoping to do it for him himself, and was amazed to find how simple and easy the whole procedure was, and he is sure this will be the experience of any of the members of this Society who may wish to try it

Dr J Ford Thompson said some of Dr Yarrow's remarks might be construed into a reflection on modern surgeons The operation of which he speaks is one of the simplest which can be performed on the urethra He himself had performed it four times within the last few months for various reasons The patients were suffering from ruptured urethra, stricture, urinary infiltration, or some other trouble calling for this operation, which is nothing more than the median operation for stone It is not the boutonnière operation devised and practised by Dolbeau That surgeon, after an incision, used dilators for widening the membranous portion of the urethra The operation as described by Dr Yarrow and as practised everywhere, cannot be a difficult one, for it would be almost impossible for the surgeon to miss the large groove of the staff previously introduced into the bladder It is much more difficult to operate without the presence of a staff in the urethra

Dr Yarrow replied that he was quite well aware that Dolbeau had invented the boutonnière operation but he also knew that Sir Henry Thompson had applied it to the removal of these tumors from the bladder He had brought this case to the attention of the Society in order to show the ease with which papillomatous growths could be removed from the bladder

Dr J B Hamilton desired to call attention to several points in the case under discussion It was of course necessary that a proper diagnosis be made In order to distinguish between hæmorrhage from the kidney and hæmorrhage from the bladder, he would suggest the exhibition of gallic acid, which would stop the hæmorrhage from the kidney, but would have no effect upon the hæmorrhage caused by a papilloma He had recently used this acid with good results in some cases of carcinoma uteri In other situations as well as the bladder papillomata recur after removal He had removed one from the cheek three times within a year—in January, May, and October last They are also prone to take on epithelial transformations by reason of cell substitution The mere removal of a papilloma from the bladder does not give assurance that it will not return

As to the method of operation, the only philosophical way is to cut through the perineum This operation is sometimes difficult and sometimes easy Last summer he operated twice on account of impassable strictures He operated without a guide In one case he was twenty minutes, in the other an hour and fifteen minutes performing the operation It is true there was a difference in the length of the strictures So it might be with the attachments of the tumor Generally, however, the operation is easy

Dr Thompson said he had that day been consulted in reference to a case in a neighboring city The tumor was described as being as large as a man's fist He related the history of a case of papillomatous disease of the rectum in which he had operated as thoroughly as possible, but unfortunately the trouble has returned He agreed with Dr Hamilton that the disease frequently takes on a malignant character

Dr Yarrow could not see that the mere fact that the tumor might recur should prevent an operation The man would certainly have died before this, and he is now more comfortable than he has been for fourteen years

Dr A F A King was glad to know that surgeons were able to treat these troubles so easily and successfully We must do the best we can for these patients, and give them the benefit of every chance He wondered if there would not be less liability of a recurrence after an early operation following an early diagnosis He thought there should be no difficulty in diagnosticating between hæmorrhage from the bladder and blood from the kidney

Dr Hamilton did not wish to be understood as speaking against the operation because the tumor may recur If he had held such a belief he would not have operated three times on the case cited

Dr Ryburn said that a diagnosis was easy soon after the tumor made some progress, from the fact that small pieces become detached and are voided with the urine The amount of tenesmus caused by the presence of such a growth in the bladder is very great He recalled some of the incidents of a case which he reported to the Society some time ago, in which the patient died after weeks of excruciating anguish Whilst the operation is an old one, it is new in its application for the removal of papillomatous growths of the bladder

Dr A Y P Garnett related the case of a female whose urethra he dilated for the purpose of applying styptics to a growth at the neck of the bladder Two applications of nitric acid were successful He thought it would be difficult to distinguish between the hæmorrhage caused by a villous thickening of the lining membrane of the bladder and hæmorrhage due to a papillomatous growth But these villi do not offer such resistance to the contractile powers of the bladder, hence when they exist there is not such thickening of the vesical walls as where there is a papilloma present

---

GYNECOLOGICAL SOCIETY OF BOSTON

Stated Meeting, November 12, 1885

The President, H O Marcy, M D, in the Chair

Dr Ernest W Cushing made some remarks on

THE RELATION OF BACTERIA TO CERTAIN PUERPERAL PROCESSES

These observations were based upon the results of examination of the bodies of such women as died from these maladies in the General Hospital at Vi enna, last spring He mentioned the great difference between the customs and rules governing the obstetric assistants and students in Berlin and Vienna In Berlin every care is taken to avoid infection, either from foul hands or instruments or from the clothing or hair In Vienna many of these precautions are omitted, and students are permitted to attend autopsies and operations on the same day Obstetric operations and laparotomies are performed before the whole class, without spray, and the chief assistants give operative courses upon the cadaver every afternoon, relying for safety upon washing, bathing, and change of clothing In spite of this seeming carelessness sepsis in puerperal cases is rare, this would seem to be an argument that puerperal septicæmia is not an entity that floats about in the air and enters the system through the lungs, etc , but that it is due to the development and propagation of bacteria introduced into the system directly from fingers, instruments or applications

As a result of the examinations above mentioned Dr Cushing stated that the most frequent cause of infection was the streptococcus, the next the staphylococcus, with which is frequently associated the bacillus pyogenis fœtidus The streptococcus occurs in chains, the staphylococcus in bunches like grapes One or other of the above species was found in every acute case, either in the iliac or uterine veins, or both In pelvic abscesses they are found in the lungs and joints wherever metostatic abscesses are found Microscopic preparations of the above were shown and specimen cases described

In the discussion of Dr Cushing's remarks the question arose in regard to the pathology of the chill which is so frequently noticed in pyæmia and other processes

Dr Z B Adams thought that in many cases the chill was not due to the presence of micro organisms, but was simply a nervous manifestation due to nerve irritation The chill which follows catheterization was due simply to the irritation of the catheter carried to the nerve centres through the nerves alone Rigors may occur from abscess when the abscess is separated from the surrounding tissues by impermeable walls

Dr Warner thought that chills are not always due to the presence of micrococci, but may be due to different causes in different cases

Dr Cushing maintained that catheter fever and the chills which precede or accompany catheterization are due to infection from foul instruments or catheters

Dr H J Harriman then read a paper on

HABITUAL CONSTIPATION IN WOMEN, ITS CAUSES AND EFFECTS

(See page 150)

Dr Warner said that the condition of the bowels should be an important consideration in the treatment of all cases Generally they will be found constipated, but careful attention to secure regular and full evacuations will often secure better results than any local treatment Whatever success he had had in treating the diseases peculiar to women was due to constitutional rather than local treatment Dr Warner mentioned a case which he had once examined for pelvic trouble where he found the rectum greatly distended by fæces The patient said that such could not be the case, as she had suffered from diarrhœa for several days It proved that a canal had been formed through the fæcal mass through which the diarrhœal discharges had taken place The speaker had used for years with great success the following pill in cases of habitual constipation ℞ Pil hydrarg , grs iii, ext hyoscy and ext colocynth, aa, gr i

Dr Wm G Wheeler mentioned the case of a school teacher who presented herself for treatment and stated that her bowels were regular Treatment was carried out for some time without any improvement More careful inquiry in regard to the state of the bowels revealed the fact that they "moved regularly once a month "

Dr Marcy mentioned a case at Block Island in which thirty one days passed without an evacuation of the bowels

The President then read a communication from Dr H C Ghent, of Belton, Texas, in which he called attention to a

NEW AND SUCCESSFUL AGENT IN THE TREATMENT OF VESICAL HÆMORRHAGE

A patient was operated on for vesico vaginal fistula Wound healed by first intention On fifth day after operation a furious hæmorrhage from the bladder occurred, and persisted for more than two days in spite of every effort for its control The loss of blood was fearful As a last resort equal parts of iced water and apple vinegar were injected into the bladder Before a pint of the mixture had been injected the bleeding ceased and did not recur Dr Ghent raises the question as to whether vinegar or acetic acid has been before used for vesical hæmorrhage

---

DOMESTIC CORRESPONDENCE

BRANCHES OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor of the Journal

Dear Sir —Some recent conversation on the subject of the formation of Branches of the American Medical Association, similar to those of the British Medical Association, has suggested the idea that some steps might be taken with this end in view at the coming meeting of our Association in St Louis That the formation of such Branches would be for the good of the profession generally, and therefore of the Association, cannot be questioned, unless we shut our eyes to the advantages derived from the system in Great Britain and her Colonies The late Guéneau de Mussy said, a short time before his death, that the British Medical Association was the greatest medical organization in the world, and it is not difficult to see that its greatness is, in great part, due to its Branches

It seems that the proper steps towards the formation of such Branches must be (1) some provision on the part of the American Medical Association by which those who are already members of the Association may form themselves into separate bodies (Branches), which shall be so constituted, and have such powers and privileges, and be subject to such obligations, as shall be determined on by the Association in general meeting; (2) a provision by which societies composed of members and non-members of the Association may, upon application form themselves into Branches, under the same rules and regulations as stated in (1); (3) a provision empowering the Branches thus formed to admit members of the regular profession in good standing to membership in the Branches, and thus to membership in the Association.

It has been suggested that the making of a large Branch of a State Medical Society would scarcely be feasible, for two reasons: 1. The members of the State Society would object to being deprived of their liberty in this way, and being made a *dependency* instead of a sovereign society. Regarding this question there is much to be said on either side. The objects of the State Societies and of the National Association are the same: the promotion of medical and the allied sciences, and the maintenance of the honor and the interests of the medical profession. The State Society would still have control of its own members, and those members would also be members of the National Association. The ties uniting the State Societies (or Branches) to the American Medical Association would be similar to those uniting the States to the General Government. There can scarcely be a doubt that the profession in the different States will be brought more closely together, and in this way the medical men of the whole country, questions and methods of medical reform will be more easily settled and prosecuted; and altogether the advantages would outweigh the disadvantages.

2. A second question as to finances would come up when it was proposed to ask State Societies to become Branches of the American Medical Association. For example, the members of these Societies pay a certain sum each year as dues, part of which is for the publication of the Transactions of the annual meeting. It might be said that every member could not well afford to pay his dues in the State Society, and his Association dues in addition to this; and consequently, if the whole State Society becomes a part of the National Association the Association should secure to the members of the Society the publication of their Transactions. Two answers may be made to this. The number of members of a State Society who cannot pay the two sets of dues is extremely limited; so small that it may be practically eliminated. Again, the value of the average State Society Transactions, as printed, is very little, and the published Transactions could be easily and even profitably dispensed with in some cases. All sorts of papers, from good to very bad, are mixed in them. In some cases the time for papers is limited, as well as the space for any one paper in the published Transactions, and the papers often go out into the world half printed, and with some important discussion or conclusions omitted altogether. There is no good reason why the business proceedings of the Societies should not be published in the journal of the Association, and let the papers be published wherever the authors may elect. Such is the plan adopted by the Branches of the British Medical Association. It could scarcely be supposed that all the papers could be published in one journal.

In great Britain the dues to the Branches seem to be comparatively small; the dues for the Bath and Bristol Branch are only four shillings a year (less than a dollar). The regulations of the Branches of the British Medical Association seems to be very similar to those of our State Societies, with the addition that each Branch has a voice in the General Council of the Association, through its representative elected at the general meeting of the Branch. (Every Branch is entitled to elect one representative to the Council, and every Branch consisting of more than 200 members is entitled to elect an additional representative member for every complete 200 members of which it consists.) It may be remarked here that the General Council of the British Medical Association is for the purpose of taking a great deal of the business details out of the hands of the Association, and thus causing a great saving of time at the general meetings.) The By-laws of the Association regarding Branches are as follows: 1. Any number of members, not being less than twenty, may form themselves into a Branch of the Association, subject to such Branch being recognised by the Council. 2. Each Branch shall be free to govern itself as its members shall see fit, but no Branch law shall be valid which, in the opinion of the Council, may contravene any fundamental law of the Association. 3. Each Branch shall pay its own expenses, and no Branch shall be deemed for any purpose the agent of the Association, or have power to incur any obligation in its behalf.

The Branches of the British Medical Association now number thirty-four, exclusive of Colonial Branches, representing a membership of about 7000 Branch members. (It should also be said that very many members of the Association do not belong to any Branch.) Can there be any good reason why the American Medical Association should not soon become as powerful as our sister Association across the Atlantic? If there be any objections to the proposed system, would it not be well to put them forward now, in order that they may be avoided or met, as the case may be? Would it not be well for some of the members of the American Medical Association to discuss the subject in THE JOURNAL, so that some action may be taken at the next meeting of the Association, in St. Louis in May? Anyone who will take the trouble to look the matter up will be surprised to see the number of physicians in this country who do not belong to any medical organization at all. Even in some of the most populous States there are numbers of counties without any medical society, and in many of the counties in which medical societies exist, there are numbers of medical men who have no connection with them. If the plan suggested in this communication should be carried out, there seems to be no reason why nine-tenths of our physicians should not belong to a

BRANCH

MUTUAL PROTECTION AGAINST BLACKMAIL

To THE EDITOR OF THE JOURNAL

Dear Sir —I have read with much interest the various expressions of opinion concerning the subject of protection against blackmail, published in THE JOURNAL of January 30 In considering such a question as this it is useless to rail at "shysters," or to assume that every action for malpractice is a case of attempted blackmail So far as my observation extends, the average lawyer is no better, and certainly no worse than the average doctor, and so long as human nature is unchanged I suppose that there will be both shysters and quacks Without doubt many cases of malpractice exist which never find their way into court, I do not think that any respectable lawyer would bring a case which he thought groundless, but I am quite certain that many medical men of apparently good standing in their profession are open to the criticism so well expressed by Dr Hotz in the discussion of Dr Doering's paper

In my opinion, much more can be done in the way of preventing suits than has been attempted This may be accomplished in several ways (a) by reputable physicians refusing to countenance such suits by abstaining from criticism, and by being a little more cautious in giving so called expert testimony, (b) by taking some pains to learn what their rights and duties are, and (c) by paying more attention to the preservation of evidence in all cases in which there is a possibility of a question of malpractice being raised

As to the association discussed in your columns, the matter deserves serious consideration While there is no doubt that membership in such an association ought not to affect the decision of the issue in a malpractice case, still there is no doubt whatever that on cross examination the fact of such membership would be made to appear To foretell the effect of such a fact upon the average jury would require omniscience It ought not to prejudice them, provided the association appear to be for the purpose of protection against vexatious and groundless actions, and provided it be made distinctly to appear that every case is impartially investigated, and the prosecution of well grounded actions encouraged instead of discouraged As to any attempt by such an association to prevent physicians from testifying in proper cases, even to the extent of disclosing professional secrets, I have no doubt whatever that, in the present state of the law, which needs amendment in this respect, such attempt would be unlawful

It is worthy of consideration, however, whether such an association might not discourage champertous contracts between attorneys and blackmailers, in other words, discourage taking cases on "spec," to use the words of the worthy Samuel Weller in the famous case of Bardell vs Pickwick, by instituting prosecutions for champerty against attorneys guilty of such practices, for there is no doubt whatever that taking such cases on shares is to day a criminal offense in this State

Some twenty years' experience in the study and practice of the law and several years' study of the subject of legal medicine lead me to think that many of the groundless suits would be shorn of many of their terrors were the defense more efficiently conducted Most lawyers are as ignorant of medicine as most doctors are of the law, and that is saying a great deal In a case in which I was interested a year or so ago, the counsel for the plaintiff, a well known trial lawyer, betrayed the most colossal ignorance of the affection in question To retain an attorney and expect to teach him the science of medicine and surgery by defending malpractice suits, as suggested by one of the correspondents, would be rather a perilous undertaking for the unfortunate defendants who happen to furnish the first series of cases—I had almost said cadavers That the attorneys do as well as they do, however, is a high compliment to the profession, but to expect that a non-medical man can be able to "cram up" on a case so as to understand the subject in all its relations, in the short time at his command, is expecting too much, they must be supplemented by the doctors themselves, or must be medical men It is manifestly impossible and highly dangerous to a cause to examine or cross examine a witness upon a topic with which the examiner is not well acquainted

I do not think that lawyers and doctors cultivate the acquaintance of one another so much as their interests require A medico legal society would be useful in this respect, but I doubt whether it could be maintained in this busy city, where the race for wealth absorbs so much attention In Continental Europe and Scotland the practice of legal medicine is rightly made a specialty If the members of the medical profession in this city would afford suitable facilities for attendance upon autopsies, etc , to such persons as feel inclined to cultivate this department, I doubt not persons could be found, both honest and capable, who would specialize in this direction At present I believe that New York is the only city in this country in which anything has been done in this direction, and I do not know to what extent such efforts there have proved successful Again, I think that our medical schools should pay more attention to the subject of medical jurisprudence So far as my observation extends very few physicians are well informed upon this important subject, and I think the fault lies with the medical colleges The subject should form a part of the course of every law and medical school, and should be taught by one who is sufficiently well informed to give the students such practical information as will enable them to know their rights and duties in advance of a suit for malpractice The doctor who studies medical jurisprudence for the first time as a defendant in a malpractice suit, or when cross examined in open court, is not most felicitously situated either for giving or receiving instruction In conclusion, permit me to suggest that a special meeting of reputable physicians be called for the discussion of this subject A comparison of views by word of mouth will accomplish more in one evening than can be done by a year's writing

I am, respectfully,

MARSHALL D EWELL, M D ,

170 Washington St , Chicago February 2, 1886

COCAINE, WHAT WAS ITS INFLUENCE IN THE FOLLOWING CASE?

TO THE EDITOR OF THE JOURNAL

Dear Sir —With the view of increasing the amount of clinical evidence as to the value and effects of cocaine, I submit the following history of a case treated in the Missouri State Lunatic Asylum No 2

Esther C, admitted October 21, 1884, aged 39 years, married 20 years, mother of four children, youngest 2½ years old She was a strong, healthy woman until four years after marriage, about which time she became affected with some uterine trouble, and was never strong and well afterwards She had never any acute serious illness Eighteen months previous to admission the first symptoms of mental derangement were observed, manifested by neglect of maternal and household duties, and by frequent attempts to leave home alone, by day and night She became despondent and melancholy, feared injury and death, destroyed her clothing and the furniture, did not eat or sleep much, had periodical attacks of excitement and violence, and threatened to kill herself and baby She had delusions in regard to religion There was no insane heredity, but her mother was an exceedingly nervous woman Her expression was anxious and distressed, and she was restless and discontented

The thoracic and abdominal organs were sound, and performed their functions very well Cervical and corporeal endometritis existed, associated with profuse vaginal leucorrhœa She was greatly depressed and profoundly melancholic, constantly lamenting and complaining that she was the most miserable of beings, and expressing a desire to change her surroundings where sympathy could not reach so unworthy and wretched an object She was removed from the Asylum by her husband in June, 1885, having remained under treatment for six months She was greatly improved, both in physical and mental condition, when removed

In September, three months after her removal, she was re-admitted in a much more deplorable melancholic state than when first she came under observation She had attempted suicide, and was completely inconsolable Her physical condition was low, the uterine disorder and leucorrhœa had re appeared, and her second state was altogether worse than the first On November 2 the use of hypodermic injections of hydrochlorate of cocaine was commenced, Dr A P Busey administering one grain at 9 A M, and the same quantity at 4 P M This was continued for thirteen successive days At this period her physical condition had improved, she was stronger and better nourished, her appetite was better, and she slept better, but her melancholy was as profound and her lamentations as distressing as usual At this time there appeared several irritable boils upon the face, scalp and neck, which was the only indication of systemic disorder

The cocaine had a pleasant effect upon her, always acting as a cerebral and nervous stimulant, and it exhilarated and enlivened her for from one half to one hour after the administration She was so pleased with its effects as to request its administration with great earnestness It always increased the pulsations of the heart from twenty to twenty five beats, and the sphygmograph uniformly indicated very considerable increase of arterial tension It did not produce nausea or loss of appetite, nor did it produce uniformly marked paleness of the surface, which is one of its chief primary characteristic effects Nothing indicating illness was noted at the time when the last evening portion was injected, but during the night she complained of pain in her head, especially on the left side, and she became restless and sleepless On the following morning the temperature rapidly increased, and the pulse also increased in frequency and force, indicating serious constitutional disturbance The surface of the extremities was pale and cool The face was discolored, bluish, turgid and puffed The eyeballs were perceptibly swollen, the eyes dull, pupils motionless, and the vessels of the ball filled with blood The left side of face was more discolored than the right There was a continuation of the severe pain in the head, and articulation and vision were perceptibly impaired She could not be aroused to give an intelligent reply to questions Delirium soon supervened The discoloration and swelling of the face continued The circulation of the extremities diminished The balls of the eyes rapidly protruded, and within a few hours they had protruded so far that the lids could not cover them The balls felt hard, dense and resisting Violent delirium passed into profound coma, which terminated fatally within thirty hours from the time the last injection was given Unfortunately, no autopsy could be obtained

The importance of this subject requires no apology for giving minute details of the case The following conclusions have been arrived at from the observed effects of cocaine, which has been administered very extensively to the insane within the past five or six months

1 It is an agent possessed of great potency It acts primarily with great power and celerity upon the cerebral and spinal nervous system, and secondarily upon the heart and vascular system

2 From its potency and rapidity of action it is liable to initiate organic lesions and functional disturbances which are uncontrollable It is not uniform in its action, and therefore is an uncertain agent

3 Its effects are too transient and unstable to become a reliable and efficient remedy in constitutional or organic diseases The aphrodisiac effects attributed to it have not been observed, neither have the intense nausea and inability to vomit been observed Its permanent beneficial effects in melancholia and allied affections are not established facts, in the writer's opinion

4 As it is an agent of great potency, and as it is under trial to determine its limits of usefulness and danger, it should be prescribed with increasing precaution and discretion GEO C CATLETT, M D,
Physician and Superintendent of State Lunatic Asylum

St Joseph, Mo, January 30, 1886

BOOK REVIEWS

Vorlesungen uber Bacterien, von A de Bary, Professor an der Universität Strassburg Mit 18 Figuren in Holzschnitt 8vo, pp vi, 146 Leipzig Verlag von Wilhelm Engelmann 1885

Bacteria By A de Bary, Professor in the University of Strassburg Leipzig Wilhelm Engelmann Chicago Koelling, Klappenbach & Kenkel

Professor de Bary is well known to bacteriologists and biologists by the three works from his pen which have already been published "Die Fruchtentwickelung der Ascomyceten," in 1863, "Die Mycetozoen," in 1864, and his greatest work, "Vergleichende Morphologie und Biologie der Pilze, Mycetozoen und Bacterien," 1884 The purpose of the little work now under consideration is to give an insight into the nature of bacteria, but the author states in his preface that one must not expect to find a complete treatise on bacteriology

The first six chapters, covering fifty pages, are devoted to the biological and histological study of bacteria in general Then comes a chapter relating chiefly to the subject of fermentation, chapter VIII is devoted to the Saprophytes The subject of fermentation is again taken up in the next chapter The remaining chapters deal with the parasitic bacteria, including a general discussion of parasitismus The harmless bacteria of warm blooded animals are discussed in a short chapter, *Milzbrand* and Chicken-cholera in one of eighteen pages, and the "Causative Relations of Parasitic Bacteria to the Infectious Diseases of Warm-blooded Animals" in one of twenty pages The last chapter concerns the "Bacterial Diseases of the Lower Animals and of Plants"

It will be seen by this short account of the scope of the work, that methods and questions of cultivation of bacteria receive but very little attention Nevertheless, the work contains a vast amount of interesting reading and positively useful material—material that cannot be obtained in such concise form in any other work of which we have any knowledge It is completed by a good index

Practical Surgery Including Surgical Dressings, Bandaging, Fractures, Dislocations, Ligation of Arteries, Amputations and Excision of Bones and Joints By J Ewing Mears, M D , Lecturer on Practical Surgery and Demonstrator of Surgery in Jefferson Medical College, Surgeon to St, Mary's Hospital, etc With 490 Illustrations 8vo, pp xii, 794 Philadelphia P Blakiston, Son & Co 1886 Chicago W T Keener

As a convenient work on practical surgery, this, the second edition, is much in advance of the first Three new sections—on fractures, dislocations, and resections—have been added, and enhance the value of the book, and the section on antiseptic dressings has, of course, been almost entirely rewritten and much improved Indeed, it is not sufficient to say that it has been much improved, since it is now a very clear and concise statement of the antiseptic methods of surgery

Of the chapters devoted exclusively to surgical technics, the one on excisions is perhaps the most pleasing, and of this chapter the part on excisions of the face This is only natural, in view of the fact that the author has won an especially enviable reputation in this particular field of surgery Though there may be a few points on which many surgeons would differ from the author, as a whole the work is excellent, the student or practitioner who follows it intelligently cannot easily go astray We could wish that a chapter had been added on operations on the abdominal and pelvic cavities, and on the operations for hernia

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE PROFESSION IN AMERICA

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

Membership —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such as long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly Journal of the Association for one year

Members by Application are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly Journal

When Dues are Payable —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the Journal for one year from the following July Payment for 1885, for example, entitles the member to the Journal from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the Journal of the Association

Subscriptions to the Journal, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph

Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

RICHARD J DUNGLISON, M D , *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

MIRYACHIT —In an editorial note on this subject the *British Medical Journal* says Etymologically the term *miryachit* is decidedly a failure, originating from a defective knowledge of Russian *Miryachit*, or, as it should be written, *miriatchit*, means literally "he or she fools," or "plays the fool" It is derived from the verb *miriatchitje* The verbal noun is *miriatchenie* (fooling or playing the fool), he or she who *miriatchit*, is *miriasha* Hence—if it be desirable to retain a Russian word—it would be more sensible to call the disease *miriatchenie*, as it is called in Russian, instead of *miryachit* (he fools) In the *Vratch*, No 36, 1885, p 602, Dr Jankovsky publishes an interesting note on an epidemic of this curious neurosis, which has come under his observation in the Littoral District of Eastern Siberia He first came to be acquainted with *miriashas* in this way One fine evening in 1876, shortly after he had been appointed surgeon to the 1st Eastern Siberian Infantry Battalion, a *feldsher* (assistant surgeon) on duty hurried to him with a startling information that fourteen "mad" soldiers had been brought to the hospital On his arrival, the author really found a crowd of the patients, and, naturally enough, addressed to them the question, "What is the matter with you?" To his greatest astonishment, all fourteen addressed him in chorus, "What is the matter with you?" He tried then to put the interrogation in another way, "What ails you?" The answer followed again, "What ails you?" In short, every word of the medical man was simply echoed by every one and all of the patients On examination, he found, in every individual case, increased apex-beat, rapid pulse, extreme nobility of the limbs, (especially of the hand), somewhat increased cutaneous sensibility, dilatation or contraction of the pupils, gay disposition, laughter, or smiling, without any reason whatever, etc While the author was examining the patients, an officer in command arrived, and informed him that all the men had had for their supper potatoes with hemp oil, the latter being bought of a Corean hawker On hearing the work "oil" (*maslo*) spoken by their commander, all the soldiers suddenly went on with repeating "Oil, oil, oil," in all possible manners, in spite of all entreaties and injunctions In view of the fact that one of the patients vomited, and after vomiting ceased to "fool," the author ordered emetics and purgatives in every case The patient, slept quietly through the night, and on the next morning all were well, being able to only vaguely recollect the events of the previous day ("as if in a dream") An inquiry elucidated that the Corean oil merchant was a *miriasha*, and that "fooling" attacked only those soldiers who had seen and spoken to him Another case of multiple *miriatchenie* was observed by Dr Jankovsky in Vladivostok in 1878, in four children of one family, aged from 3 to 7 years Sporadic cases of "fooling" were met with by him very often As a rule, the disease is chronic, and apt to spontaneous remissions It begins mostly under the influence of contact with a *miriasha*, but sometimes is hereditary It attacks only natives and "well acclimatised" immigrants, and here again only children and subjects of a "low intellectual level" The general health of the *miriasha* remains intact The disease usually does not interfere with the occupation of the patient It is obviously a form of "epidemic male hysteria"

PROGRESS OF SMALL-POX AND CHOLERA —From the circular of the National Board of Health, dated January 27, 1886, we take the following results of small pox in Montreal up to January 20, 1886 During the week ending Jan 21 there were 10 deaths in the city and 6 in its suburbs The total number of deaths from small pox in the city of Montreal from the beginning of the epidemic in April to December 31, was 3,164, as follows In April, 6, May, 10, June, 14, July, 46, August, 239, September, 659, October, 1,393, November, 633, December, 165 There were also 363 deaths from measles, typhoid fever and diphtheria during the year, and the total mortality from all causes during 1885 was 7,885 as against 4,358 during 1884 Consular reports from different parts of Europe show that the disease is decidedly declining as a whole

From the same sources we learn of the continued prevalence of cholera moderately in the Province of Huelva in Spain, and in the single Department of Finisterre in France

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM JANUARY 23 1886 TO JANUARY 29 1886

Col John I Summers, Surgeon U S Army retired from active service by operation of law, Jan 24, 1886 (S O 20, A G O , Jan 25, 1886)

Major Wm L Waters, Surgeon, granted leave of absence for one month and fifteen days (S O 5, Div Atlantic, Jan 23, 1886

Asst Surgeon J M Banister, ordered for temporary duty at Ft Warren, Mass (*S O 16, Dept East, Jan 23, 1886*)

ORIGINAL LECTURES

EPILEPSY—TORTICOLLIS—IRRITABLE HEART

A Clinical Lecture Delivered in the Jefferson College Hospital

BY ROBERTS BARTHOLOW, M D ,
OF PHILADELPHIA PA
PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE JEFFERSON MEDICAL COLLEGE

We have here a woman approaching the climacteric period, who tells us that she has had four well marked attacks of convulsions since she was 17 years of age, the last one occurring at night when she had several convulsions, between these well marked attacks she has frequent less severe "spells," characterized by vertigo, more or less confusion of thought and speech and some staggering She belongs to a neurotic family, in several members of which there is a well-marked history of epilepsy

We have, as you know, two varieties of epilepsy, *petit mal* and *grand mal*, between which there is a vast gulf, a vast chasm separates the words epilepsy and epileptiform As a rule, true or essential epilepsy begins at puberty, while epileptiform seizures may commence at any period of life If the seizures begin at the age of 30 or 35, they are most likely dependent upon some organic disorder, and very frequently it is a tumor of the brain In true epilepsy there is not always discoverable any gross lesion, though of course some lesion must be present, and it can occasionally be found Habit, in neurotic persons, may be a cause, that is to say the nervous system forms a habit, just as there is a habit of taste or smell or any other kind of a habit, but, of course, habit plays but a small part in the causation

When investigating epilepsy we must always look out for some reflex cause, inquire about the aura, which may give some clue to the origin, though it is rarely present, and when it is the sensation is usually referred to the stomach It is of the utmost importance to inquire at what times the attacks occur, much more important than you would suppose, for attacks that occur at night are much less amenable to treatment and are much more obstinate Mild seizures and those occurring at long intervals are likewise very obstinate Those attacks that occur in the day time, with great violence, and are directly traceable to some cause, are the most satisfactory because we can usually relieve them by removing the cause They are not infrequently due to the irritation from an overloaded stomach, we must always look for outside disturbances and remove them

If there be any secret in the treatment of epilepsy, it is in regulating the diet I am sure that more good has come from attention to this one point than from anything else I am quite sure that it has worked many cures, drugs have a trifling potency compared with a rigid diet The meals must be small at a time, meat only once daily, and the stomach should never be overloaded, while large draughts of liquid must be avoided, even of water Fatty food should be interdicted, and but small quantities of starchy or saccharine matter allowed For drugs, we must remember that this woman is approaching the climacteric period and that the attacks are growing worse, hence our drugs must be directed towards allaying any irritability of the sexual system This can be best accomplished by the use of bromide of sodium, of which we will order one drachm, morning and evening, for the first week, and after that one drachm daily, in two doses We will also look to all the other functions, and if we find any derangement we will remedy it

Torticollis —This might seem, at first blush, like a trifling case to bring before you, but it offers some very interesting points I have repeatedly impressed upon you the importance of studying the physiognomy of disease, and this case serves to point the remarks An acute observer could make a diagnosis in this case without asking a question The external expression of parts, the features will reveal much, and it will repay you to cultivate the habit of close observation You may recall the old adage, "Show me your ear and I will tell you who you are, whence you came and whither you go" There is much in the idea conveyed by this adage, and you should not forget it Now when I look closely at this woman, I notice that she holds her head in a constrained position, when at rest it is drawn somewhat backwards towards the right shoulder, and there is more or less spasm, more or less involuntary movement By an effort of the will, you will notice that she can keep her head straight before her, the sterno cleido mastoid muscle is rigid, as is also the trapezius, the anterior edge of which stands out The muscles of the opposite side seem relaxed

We have here, then, a case of torticollis, which is one of the most difficult diseases among the minor ills to treat, which statement I am very sure you will verify after you have been a short time in practice The muscles of one side are in a state of spasm in this disease, while those on the other are paretic. One set of muscles are acting over powerfully, the seat of the disease being in the nerves that supply the muscles, there is an irritation of the motor nerve, and this irritation excites the muscle to spasmodic contraction. In every voluntary movement there is a contraction of the muscle under the stimulus of the will, but here the will is in abeyance, the over-acting muscles are hypertrophied, while those on the opposite side are atrophic, the disease is therefore secondary to an irritation of the nervous apparatus.

All kinds of remedies have been used in vain, but we can do so much in these cases by attention to little details and can cure the disease if it has not lasted too long. It has been present in this case for a year. The first point is to look for a cause of irritation to the nerves, is it impinged upon by a tumor, a gumma? If so we have clear sailing. May be the irritation may be reflex from the uterine system, as is not uncommon, and in such cases, of course, we can do nothing towards a cure until we remove the uterine trouble. It is a fact that I have observed that torticollis is especially common among women, and in many of these cases it is associated with uterine trouble. This woman is 49 years old and is now passing through the change of life, it having been seven weeks since her last sickness, the uterine irritation about the climacteric period is a not uncommon cause. Inquire always whether it is due to any disturbance of the stomach or intestinal canal, or whether it is purely neurotic from the climacteric, I am inclined to lean to this latter view in the case before us. We must address our remedies, therefore, to the nervous system of the climacteric. Galvanism and faradism will do a great deal of good, and the best procedure is to galvanize the overacting and faradize the underacting muscles, I will use fifteen cells of a small battery, applying the steady, non-interrupted current on the contracted muscles, and the interrupted current on the paretic muscles, I prefer the slow interrupted current, for the rapid interruptions will throw the muscles into a tetanic condition, the slow current should be applied to each muscle in turn and must be used regularly and perseveringly every day.

A great deal can also be accomplished by gymnastic training under the direction of the will, which should be used to educate the weaker muscles to antagonize the stronger, it is wonderful how much can be accomplished in this direction by the force of the will. All drugs that have a reputation for controlling muscular spasm have been tried in this affliction, and hyoscyamus and gelseminum have done some good, but they do not cure. Arsenic thrown directly into the muscle, by hypodermic injection, has done more good than anything else, its use was begun empirically, because it was known to do good in chorea, which is a disease somewhat analogous to torticollis, some very obstinate cases have been thus cured by arsenic. Cocaine, the drug of the day, has also been used with advantage, injections of one-sixth or one-fourth of a grain being made. While these injections are being made into the contracted muscles, strychnia should be similarly used in the paretic muscles. By these combinations we can generally cure the disease, if there be no lesion of the nerve, but we will find it a very obstinate disease to handle.

Irritable Heart.—Here we have a pale, anæmic woman, in a state of constant nervous tremor, who was told some years ago that she had hypertrophy of the heart, and who ever since has lived in constant fear of a sudden death, afraid to go to sleep, afraid to leave home, unable to perform her domestic duties, and with life a burden to her. She is now at the climacteric period, but she was excessively nervous even before this time. Upon examination I find simply a highly irritable nervous system, which I believe to be mainly due to the high condition of anæmia which the woman presents. She has a neurotic temperament. The heart is not irritable as we see it in exophthalmic goitre, where it continually pulsates at the rate of one hundred or more, her heart, while it is now, under excitement, beating at the rate of one hundred or one hundred and twenty, will, when she is quiet, drop down many beats, but the least emotion will make it drive ahead at a very rapid rate. There is of course some hypertrophy, but this is due to the excessive action of the heart, it is compensatory, it is physiological, and does not constitute a disease. The anæmia which deranges the nervous system is in turn due to digestive disorders, which we find evidenced by heart-burn, acidity and regurgitation of food, she has an insufficiency of diet and poor digestion, there is a degeneracy of primary and secondary assimilation.

It is idle to try to relieve this condition of the nervous system, unless we supply it with good blood, it cannot be done with drugs alone, the nervous system must have good blood, we cannot so change this system as to make it functionate as it would in a person of lymphatic temperament, but we can greatly moderate its erratic manifestations, we can quiet it. We will commence by giving this woman ten drops of dilute nitric acid thrice daily, in a little while we will order her a more generous diet, prescribing especially milk and eggs, interdicting stale bread (of which she eats a great deal), and coca shells (which she drinks), because she cannot digest the fats, this I know because the eructations or regurgitations are of an offensive acid character, butyric acid is set free.

We must also leave out starchy, saccharine, and all fermenting foods. Nutrition must be forced, she should have milk every three hours, eggs daily, and meat at every meal, and of meat she should have fresh beef, game and poultry (except veal and duck), fresh fish, no salt meat or salt fish of any kind. She should eat but little bread, substituting for it such vegetables as celery, lettuce, or spinach, those that are free from sugar or starch. I am in the habit of telling such patients to eat lettuce in the English fashion, that is, to take out the centre leaves and dip them in salt. If the patient can have cod liver oil, without its producing acid indigestion, it should be given in doses of one drachm in half an ounce of whiskey thrice daily. I say whiskey with reluctance, and would not order it at all if this woman were only eighteen, but at forty-nine there is not so much danger of establishing a bad habit A person at fifty years of age, who has led a temperate life, can take a little whiskey as food, as alcoholic food, with advantage, but it will do no good to one who has been a toper It is, when properly used, an admirable food, quickly oxydized, and it helps primary assimilation

Oxygen must also be ordered, not as "compound oxygen," the greatest imposition of the day, but oxygen as we have it in the open air I am frequently asked my opinion about "compound oxygen," and when I explain that the ordinary atmosphere is only compound oxygen my inquirers are amazed to think how foolish they have been to pay a big price for that which they could obtain for nothing Exercise should be enjoined just at the end of digestion, when the food is ready to be assimilated and requires an abundance of oxygen to complete the metamorphosis

Exercise should not be indulged in just after a full meal, for at that time the blood that exercise would call to the muscles or brain-work to the brain is required in the stomach to aid digestion If this woman will follow my advice she will be relieved entirely, and the demon that has haunted her for years will prove no demon at all, for there is here only a normal hypertrophy, such as we see in the blacksmith's arm from excessive use

SOME REMARKS ON THE MANAGEMENT OF PROTRACTED FIRST STAGE OF LABOR[1]

BY HENRY DAVIDSON FRY, M D,

OF WASHINGTON D C

I am led to select this subject for discussion chiefly because of my belief that the proper management of the first stage of labor is more neglected than any of the processes connected with the child-bearing act

Sufficient attention is given to the elucidation and treatment of all the conditions, natural and unnatural, that do and may arise during the progress of the subsequent stages The consequence is that the general practitioner is ever ready to lend assistance at such times, whilst in the first stage, supported by precept and habit he preserves a passive indifference, waiting, like Micawber, not "for something to turn up," but with equal patience *for the womb to open* During the weary hours that his patient is suffering these pains he seems content to limit his duties to the occasional examination of the case, and even this is done more for his own comfort than his patient's, the object being to form some idea when his services will be required

An explanation, in part, for such inactivity is thus given by Lusk[2] "There is an erroneous opinion that, so long as the membranes are unruptured, this condition (the first stage) may be allowed to go on indefinitely" To add to the prevalence of such a dangerous opinion so able an obstetric writer as Leishman[3] gives the following advice "And, even in cases where its duration is prolonged far beyond the average, this of itself is no excuse for interference, unless the general symptoms indicate that it is our duty to accelerate the labor by such means as are within our reach—a state of matters which is of rare occurrence" Practically the same statement regarding the trivial consequence of prolonged first stage is made by Playfair[4] and by Cazeau[5] In his opposition to this view Lusk[6] continues "There is nothing that requires more judgment in midwifery practice than to decide when the time has arrived at which delay is fraught with more danger than active interference For my own part, I believe that many fair lives are needlessly squandered because of excessive timidity begotten of imperfect obstetric teachings" Delay cannot be otherwise than fraught with more danger than active interference when that interference is in itself harmless The majority of the various remedies recommended for accelerating the dilatation of the os can do no injury unless most inappropriately employed The few that cannot be classed with these may be reserved until, as Leishman has said, "general symptoms indicate that it is our duty to accelerate the labor"

It is as unwise as inhuman to allow women to suffer the pains of the first stage of labor when protracted for hours beyond physiological limits The loss of sleep, the want of nourishment, the anxiety of protracted labor, and above all the nervous depression produced by pain, all these tend to exhaust the patient and prepare the way for uterine inertia Post-partum shock and hæmorrhage, septic infection, and least of all, a slow convalesence, are some of the *sequelæ* of protracted first stage An analysis of the histories of those labors which are terminated by instrumental interference will demonstrate that very many are preceded by slow dilatation of the os The happy issue of many a case of labor is dependent, I firmly believe, upon the appreciation of these facts and the result of timely interference exercised in the first stage as well as in later ones

At the meeting of the American Medical Association held in this city in the spring of 1884, Dr Lusk read a paper "On Sudden Death in Labor and Childbed" The following case furnished a theme for his subsequent remarks On the morning of January 1 he had been called to attend a young woman aged 23 years, who was suffering the pains of her first confinement The parts were very sensitive to the touch, the head presented, and the cervix was beginning to dilate He ascertained that labor pains had been recurring since the preceding afternoon, and that his patient had passed a sleepless night The head was low in the pelvic cavity, but labor dragged along so slowly that little progress had been made at eleven o'clock

The head was dilating the cervical canal without the formation of the bag of waters Dr Lusk administered sufficient chloroform to obtund the sensibility of the vagina, and lifted the head from contact with the cervical walls. The bag of waters then formed and dilatation rapidly followed. At about two o'clock in the afternoon forceps were applied and delivery effected without further trouble. Post-partum hæmorrhage was promptly arrested by a hot vaginal injection. Alarming symptoms developed, the wrist became pulseless, the extremities cold. A temporary improvement encouraged false hopes, and in four or five hours after delivery his patient was a corpse. Dr. Lusk then took up for consideration the various causes that may give rise to sudden death after labor. The symptoms of the entrance of air into the circulation, of thrombosis and embolism, and of nerve exhaustion and shock were carefully reviewed, and the unhappy termination of the case was attributed to the latter condition. The interesting paper was concluded by these significant words, "As the nervous organization of woman loses in powers of resistance as the penalty of a higher civilization and of artificial refinement, it becomes imperatively necessary for the physician to guard her from the dangers of excessive and too prolonged suffering. Especially I would raise my voice in warning against the current opinion that the length of the first stage of labor before the rupture of the membranes is a matter of indifference, a teaching which I believe has cost the lives of many women, in a few, death resulting from shock, in more, the exhausted condition in which the woman is left after childbirth rendering her an easy prey to the perils of the puerperal state."

Before offering in review some of the means at our command for accelerating dilatation of the os, I invite attention to a few facts connected with the mechanism of this stage of labor. During pregnancy we recognize the existence of two processes, first, the growth of a body to be expelled, and second, the growth of the organ which is to expel it. The fecundation of the ovule is followed by segmentation, and, in rapid order, the developmental changes of embryological life. With the beginning of fecundation the musculature of the uterus develops rapidly. The hard fibrous character of the uterine wall becomes replaced by a highly sensitive, soft, muscular structure. From the early months of gestation to the advent of labor this muscular organ is undergoing constant contraction and relaxation, as if impatient to expel the contents. As pregnancy progresses the contractions increase in strength, and often imperceptibly merge into true pains of labor. Several weeks preceding labor the uterine tumor with its contents settles into the pelvic brim or canal, and certain preparatory changes take place in the tissues of the cervix. They become softened and œdematous, and the canal is obliterated.

The first object to be accomplished by intermittent contractions of the womb is dilatation of the cervix. The muscular apparatus is much less developed here than at the fundus, it has fewer circular fibres, and is further weakened by an opening in its wall. The compression of the contents of the uterus, which is coincident with each contraction, causes this part to bulge because it offers less mechanical resistance. The lower segment of the uterus becomes softened and thinned, and the internal os is gradually dilated. Contractions of the longitudinal fibres of the cervix also tend to pull the os open. A similar action is possessed by the uterine ligaments when descent of the uterus favors their coming into play. Each contraction is accompanied by tension of the membranes stretched over the os, which, as the os dilates, become more and more convex. The support afforded the bag by atmospheric pressure being less than the intra-uterine pressure, the decidual membranes are slipped down and protruded into the vagina. The difference of the two forces increases as the os enlarges, and consequently the bag of waters forms more quickly after a certain degree of dilatation has occurred. The mechanism is similar to the action of cupping glasses, the rarefied atmosphere within the cup representing the intra-vaginal pressure. The same forces continued after rupture of the membranes give rise to the formation of the *caput succedaneum*. The protrusion of the bag with each uterine contraction furnishes an efficient hydrostatic wedge for aiding further dilatation of the opening.

If the presenting part of the fœtus be a favorable one, and no disproportion exists between it and the maternal passage, the lower segment of the uterine wall becomes closely applied and both engage within the pelvic canal. The best example of this is met with in head presentations, particulary in primiparous cases when the presenting part, enveloped by the uterine neck, is often observed nearly or quite down to the pelvic floor at the beginning of labor. Rupture of the sac now gives passage to the "forewaters," while the amniotic fluid surrounding the fœtal body is in great part retained. This condition, viz. the engagement of the presenting part and the lower segment of the uterus within the brim or canal, has an important bearing upon the question of artificial rupture of the membranes.

Having glanced at the mechanism by which dilatation of the os is effected, we are now prepared to formulate the conditions favoring a normal first stage. These are:

1. Regular intermittent contractions of the uterus, which, besides possessing the requisite degree of strength, must act in a line parallel to the axis of the pelvic brim. The latter condition is necessary in order that the force of the contractions may be made to impinge upon the tissues surrounding the os.
2. A softening and thinning of the structures of the cervix and lower uterine segment.
3. The formation of the bag of waters.
4. Descent of the uterus in order that the dilating influence of the sacro- and vesico-uterine ligaments may come into action.

Weak contractions of the uterus are witnessed in first labors occurring in very young or old subjects. Rapid child bearing and preexistent pathological conditions of the uterine structure are some of the influences leading to such a result. Feeble contractions are likewise dependent upon over distension of the uterine walls by excess of amniotic fluid or the presence of twins. Contractions, although strong, may be inefficient because irregular and spasmodic. They are generally short and cramp like in character, with little period of repose intervening. Often associated with these are mental emotions, nervous excitement, a filled bladder or loaded rectum.

Organic softening and thinning of the cervix may be prevented by pathological conditions of the tissues. Adhesions existing between the decidual and uterine membranes near the internal os may be the means of preventing the formation of the bag of waters. Paucity of amniotic fluid and the early engagement of the presenting part within the pelvic brim are additional obstacles to such formation.

Failure of descent of the uterus and its fixation in the axis of the pelvis arises from malformation of the pelvis, or from some disproportion between the diameters of the presenting part and pelvic brim, or from the axis of the uterus and that of the pelvic brim not being parallel.

Such a list, incomplete as it is, of the various conditions that may interfere with the physiological progress of the first stage of labor, conveys some idea of the complications to be overcome by treatment. It further teaches the importance of ascertaining the cause of delay in any given case before attempting a plan of action. No fixed rules are laid down to guide us. Individual experience and close observation will most likely enable us to detect the nature of the perturbating influences which retard dilatation and will point out the line of treatment most likely to meet the demands of the case. "Trifles light as air" appropriately used will succeed when powerful means may not only fail, but do harm if injudiciously employed. The following case illustrates this point:

I was called to see Mrs. P— at 5.30 A.M. of May 21, 1885. Labor pains had commenced the day before and had annoyed her at irregular intervals since. She had not considered it necessary to send for me until just before the hour mentioned, when, while sitting in a chair, a sudden gush of water saturated her clothing. She retired, and when I arrived, the pad upon which she was lying, which consisted of four thicknesses of a quilt, was wet to the rubber cloth beneath. Examination revealed the os dilated as large as a silver dollar, the head was presenting, *and the membranes were intact*. The vagina was moist, but no fluid came away during the examination. The pains had ceased with the appearance of the discharge. I directed her to stay in bed and to send for me on the recurrence of pain. Not having received any message I called about noon, and found the same condition of affairs existing. Two grains of opium, which were ordered to relieve her of irregular pains, restored quiet, she slept some, and was comfortable until midnight, when labor set in. About one o'clock another discharge of water occurred, and I saw her an hour later. The bag of waters was ruptured and the head was engaged in the upper part of the pelvic canal in the right occipito anterior position. The os was dilated as large as the rim of a tea cup, its margin was thinned and the superjacent tissue moist, soft, and dilatable. While verifying the position of the fœtus by means of abdominal palpation, it was discovered that the whole globular mass composed of the gravid uterus was deviated to the right of the median line. For the next half-hour, during which she was allowed to remain upon her back, strong contractions produced no appreciable change. She was directed to turn on her left side for the purpose of overcoming this uterine obliquity, and in ten minutes the head was at the vulva.

The proper course to pursue in this case was plainly manifested and promptly yielded its result. If the cause of delay had been misinterpreted and oxytocic remedies administered, or any inappropriate method adopted to hasten delivery, harm might have resulted; at any rate the above happy termination could not have been looked for. This was the patient's tenth confinement, and the preceding pregnancies had so distended and relaxed her abdominal parietes that sufficient support was not afforded to keep the gravid uterus in its proper position. The first discharge of fluid which occurred in such large amount twenty four hours before labor I should study under the head of hydrorrhœa gravidarum, a subject which has been worked up thoroughly by a fellow member of this Society—Dr. T. C. Smith. I would add that the expulsion of the offspring was followed by considerabe amniotic fluid.

Treatment.—The most important of the remedies at our command for accelerating the first stage of labor will be considered under three separate classes:

First. Pain stilling agents.

Second. Remedies employed to increase uterine action.

Third. Remedies applied directly to the os to assist its dilatation.

This division of the subject facilitates its study, but is open to the objection of inaccuracy. Remedies of the first class often increase uterine action, and any direct application of methods to the os most certainly do. In fact, much of the good effect attributed to the latter class doubtless owes its efficacy to increase of uterine action.

I. In the first class are placed opium chloral, and anæsthetics. The most signal benefit follows the employment of these agents in suitable cases. Most confidence can be placed in them when delay accompanies irregular and spasmodic pains, and when weak contractions are the result of depression and loss of rest from protracted suffering. It has been my lot to see dilatation of the os begin promptly, and labor soon completed after the administration of a few doses of chloral, when seventeen hours of delay had previously witnessed no progress of the first stage.

Opium must be given in full dose by mouth, by rectum, or by the hypodermatic injection of morphia, chloral by mouth or rectum. The administration of either of these is followed, as a rule, by one of two effects. There may occur the immediate conversion of the ineffectual pains into such as produce a favorable impression upon the unyielding os. Nervous excitement gives way to quiet, the duration of the pains is lengthened, and the intervals of repose are periods of recuperation.

The other effect is *rest*, that is, the cessation of uterine contraction for one, two or more hours, probably with sleep, and then the return of pain and satisfactory progress of dilatation. It is a common experience to witness the cervix relax and dilate during this period of repose Some writers, among them Playfair,[8] deny that chloral possesses this power to annul uterine action, and attribute the beneficial influence of the drug to the former of the two effects above mentioned On the contrary, I have distinctly seen such controlling influence follow its administration Only recently a case came under observation in which 40 grains, given in two doses, produced entire cessation of pain and caused sleep during the most part of the succeeding four hours At the end of that time regular and strong contractions set in, the labor, which had lingered all night, progressed rapidly, and in less than two hours the infant was born The os softened and dilated during the repose

Anæsthesia, particularly by chloroform, is, at times, the remedy *par excellence* The following history demonstrates the class of cases in which chloroform may be used with the best prospect of success Such labors usually occur in primiparæ, and in women of highly sensitive nervous organization

Case —On Sunday, at noon, Mrs N P , a primipara, was taken with labor pains which were short, sharp, and returned every four or five minutes At eight o'clock in the evening I found the following condition The head had descended almost to the floor of the pelvis and presented in the R O A position, the os was the size of a ten cent piece, and the membranes were drawn tightly over the opening during the pains The contractions were so frequent and painful I ordered 30 grains of chloral to be taken in two doses The effect was to compose her and cause drowsiness for awhile, but not to lengthen the intervals of the pains At 1 30 A M she became nervous and declared she could stand the suffering no longer She shrank from vaginal examinations in consequence of the painful condition of the parts, the genital canal was dry, the os thin and wiry at its border, and dilatation but little increased The hypodermatic injection of ¼ grain of morphia sulphate was given without any apparent result The pains continued to recur frequently, to last but a short time, and were accompanied by unusual suffering

3 A M —Examination with finger still caused excessive pain, the head was in contact with the perineum, and the os was thin and dilated the size of a twenty five cent piece The suffering was so great, and chloral and morphia having failed to bring relief, I determined to try the effect of the inhalation of chloroform It was magical She no longer complained of pain, the contractions increased in strength, they lasted longer and recurred less frequently As soon as one passed off she dozed until the next awakened her At no time did she inhale sufficient chloroform to produce unconsciousness, she could tell when the contraction reached its acme, and when it was declining

3 45 A M Vaginal examination caused less distress and the parts were moist More progress was made within this hour than had been the case during the preceding fourteen hours of suffering The bag of waters was formed and protruding, and the os was dilated to the size of a silver dollar Composure had taken the place of her nervous excitement In one hour and a half only half an ounce of chloroform had been administered

4 30 A M The strength and duration of the contractions were increased, mucus flowed from the vagina, and the os continued to dilate At 5 o'clock the chloroform was withheld for a time and then employed intermittingly until the end of labor

At 7 o'clock, four hours after commencing the use of chloroform, the child was born

II Remedies to Increase Uterine Action —Of this class I will refer briefly to electricity, the introduction of the soft bougie, and artificial rupture of the membranes The administration of ergot during the first stage justly finds little favor at the present day Quinine is highly recommended by some for its power of restoring strength to the weakened constructions Manual pressure, so successfully employed by Playfair, is more applicable to the expulsive stage

Attention is now being directed to the value of electricity in obstetrical practice, and from the published accounts of its action upon the gravid uterus excellent results may be expected to follow its use One of the most interesting articles that has been written upon the subject recently is from the pen of Dr W I Baird,[9] of Texas Among the indications for its use he states "That dilatation of the os is greatly facilitated, thereby shortening the labor in every stage " "This effect," he says, "I have constantly observed in all the cases which I have treated with the current, and it is easy to see that it follows as a consequence that, if the current will increase the force of the contractions of the longitudinal and oblique fibres of the uterus, the os will be more rapidly developed " His results were obtained by use of the faradic current, the positive pole being applied to the lumbo sacral region and the negative to the fundus uteri An opportunity was recently presented to make a fair test of its value, and the effect was very decided in increasing the force and efficiency of the contractions, but I am sorry to admit I did not witness the wonderful sedative influence of the current as described by Dr Baird

The introduction of a soft bougie between the uterus and the membranes is an efficient means of increasing feeble contractions It is best made use of when the membranes are intact, at any rate before the amniotic fluid is drained away

Warm vaginal injections not only soften the os and assist dilatation, but also increase uterine action By adding an antiseptic to the water they exert a two fold influence for good, and are particularly useful when, at the same time, other means are resorted to which require manipulation of the cervix

Artificial rupture of the membranes is undoubtedly the most frequently employed of all the means for increasing pains and accelerating the first stage of labor The procedure is by no means harmless When the presenting part of the child is closely applied to the lower segment of the uterus, and when the pains have pushed both down into the pelvic canal, it may be justifiable to rupture the bag, *pro*

[9] American Journal of Obstetrics Vol xviii Nos iv, v and vii pp 337, 481, and 719

vided other means have been tried and failed It is particularly called for when weak contractions result from overdistension and when delay is caused by adhesions between the lower uterine wall and the decidual membranes, preventing the os from retracting over the presenting part It is wiser, under the circumstances, for the physician to hesitate before adopting a plan that favors laceration of the cervix, the immediate and remote evils of which are too well known More reprehensible is its performance when the os is high, and when the presenting part does not engage in the brim

III The last class embraces *means applied directly to the cervix to facilitate dilatation* Most important of these are Barnes' bags, manual dilatation, and efforts to correct displacement of the os, and to favor the formation of the bag of waters Lusk recently presented before the Obstetrical Society of New York a pair of forceps which he had designed for dilating the os This instrument differs from the narrow-bladed forceps of Taylor, which is intended to pass through a partly dilated cervix, and draw the head into the canal I will call attention only to a few points One is, the excellent result that often follows so simple a manœuvre as drawing a displaced os in the line of the axis of the pelvic canal Such a change places the part in the most favorable position to receive the force of the uterine contractions The most common condition calling for this interference is the backward displacement of the opening with the thinned anterior lip covering the presenting part The finger should be passed into the os, and the part drawn forwards and held in place until the malposition is corrected Lateral displacements require the same attention The abdominal bandage may be needed in a few of the foregoing cases to correct the position of the fundus, or the same result may be obtained by changing the decubitus of the patient Pushing up the anterior lip when caught between the presenting part and the symphysis pubis is a well recognized procedure

Valuable assistance can sometimes be rendered by making efforts to favor the formation of the bag of waters When failure is the result of paucity of amniotic fluid little, of course, can be done to remedy the difficulty When due to adhesion of the decidual and uterine membranes these must be broken up by sweeping the finger around the inner surface of the uterus as far as it can reach When the head is early engaged and prevents the fluid from passing to the bag, the presenting part must be raised and held until the pouch is felt

Having enumerated and classified the principal remedies employed for protracted first stage of labor, I will conclude by hoping that the members of the Society will discuss the question and give their views concerning the following points

1 How great are the dangers of protracted first stage of labor, and is it advisable to interfere?

2 What proportion of cases require such interference?

3 Individual experience regarding the most efficient remedies, and the indications for the use of each

---

OPERATION FOR CONGENITAL CATARACT IN TWENTY-FIFTH YEAR, VISION SLOWLY ESTABLISHED

BY JULIAN J CHISOLM, M D ,

PROFESSOR OF EYE AND EAR DISEASES IN THE UNIVERSITY OF MARYLAND
AND SURGEON IN CHIEF OF THE PRESBYTERIAN EAR AND EYE
CHARITY HOSPITAL OF BALTIMORE MD

That children are born blind with cataract is a matter of every day observation That these cataracts can be removed by absorption under surgical procedures is the experience of every ophthalmic surgeon and that infants who have been operated upon for cataract can, when old enough, learn to read with proper glasses, has long since been established by thousands of witnesses The acquisition of sight to those born blind is now, therefore, no novelty Experience has also taught the surgeon that if good sight is to be secured to those born blind with cataract, the operation for the removal of the obstruction must be done very early in life If the cloud in the pupil be allowed to remain for too long a time, during the growth of the child, the retina seems to be arrested in its development by the absence of its normal stimulus, strong light, and the needful sensitiveness of this membrane for good seeing is never acquired even when glasses have been carefully adjusted Very rarely is useful vision secured to adults who have remained blind throughout their entire growing life, and hence the case now reported of blindness to the age of 25 possesses peculiar interest

W B, aged 25, was brought to me in July, 1882, for cataract operation Soon after birth it was discovered that his pupils were not black but were of an ashy hue, which became the more conspicuous with his growth, and was finally diagnosed as congenital cataract When the blind child had attained two years of age his parents allowed an itinerant oculist to operate upon one of his eyes by the needle puncture He had promised to make the child see, but as iritis supervened and the pupil became closed, the operation proved a failure This accident discouraged the parents and they refused to allow the other eye to be operated upon When the boy attained a suitable age he was sent to the Virginia State Blind Asylum, and was there educated He was taught, among other things, to cane chairs, and when he arrived at manhood this became his daily occupation When 25 years of age, having heard what wonderful things were being done by modern surgery, the desire to see took possession of him, and with it came the hope that even he, blind as he had been from birth, might be made to see the forms which up to this time he had only known by feeling He sought the advice of a clerical friend, now the Assistant Bishop of the Episcopal Church in Virginia He brought him to my office and asked that the cataract be removed

I found the eye previously operated upon lost, with no light perception remaining The pupil was closed, the anterior chamber effaced, and the eye so disorganized by the former inflammation that there was nothing left of it but its name The other eye had good light perception, and barring the white pupil seemed well formed and promised some results from operation. I explained to him that the operation was not a difficult, dangerous nor painful one, and that his prospects for a successful extraction of the cataract were good, but that the retina may have lost nearly all of its sensitiveness, and that therefore he should not expect too much from the operative procedure. Under chloroform the lens was extracted through an upward iridectomy. No complications followed upon the operation. By the ninth day the wound had healed and the bandages were permanently removed. When examined the pupil was comparatively clear and the eye exhibited very little injection. There were a few opaque shreds of capsule in the pupil, but not enough to interfere with the functions of the eye if the retina and optic nerve were in good condition.

He returned to his home one month after the operation, sadly disappointed that he could not see. When asked what difference there was between his present condition and his former state one month ago, he said that light appeared to him very much intensified, and that he could now detect the shadow of any body between him and the light, but that he could not recognize outlines of any object whatever. Sad at heart he went back to his old trade, at which he had become quite skilled, and I heard of him six months afterward as being lead about, in the absence of useful sight to guide himself. I had put his case down as one from which no good was now to be expected, and therefore dismissed him from my mind.

Early in January, 1886, three and a half years after the operation, I was visited by the Bishop, who in the course of conversation asked me whether I had heard of the sight which my patient had finally secured. He told me that he usually spent a part of his summer vacation in the neighborhood where this patient resided, and as he had always taken the deepest interest in his welfare, made it a point to visit him annually and watch his progress. For the first year after the operation the improvement was not great, so that he could not trust himself alone. The definition of large objects seem to dawn upon him very slowly. It took his retina two years to acquire sufficient sensitiveness to detect large objects and to permit him to avoid them in moving about. After two years he could walk alone, and now rides horseback all over the country. On the last visit the Bishop was delighted to note a marked improvement. His vision had become sufficiently acute to detect comparatively small objects, and even the alphabet had been conquered, and the reading of very large type had been acquired. He had secured the aid of interested friends who were instructing him in reading. A book of large print, letters one fourth of an inch long, had been procured. In this, aided by a two-inch magnifying lens, he could read with some facility. It has taken him nearly four years to attain this degree of useful sight. This progress marks clearly the slow development of retinal sensibility, and from it we may expect that time will still further improve his vision.

I have not seen the patient since he left me for his home, 300 miles away from Baltimore, now nearly four years. The operation, as far as the cataract extraction went, was a success. Before he left me I could detect no abnormal changes in the fundus of the eye with the optical microscope. To what extent the peculiar functions of the retina had undergone development I had no means of determining. As he had no conception whatever of objects beyond what the handling of them would give him, I did not expect him to see or appreciate them immediately after the operation. If the acquisition of sight could be attained I knew that it would be of very slow development. Professional experience had taught us but little in this direction, and surgical reports were not rich enough in such material to give data upon which to build hope. The results of three years' development has put him further on the road to secure good vision than I had imagined possible.

I had previously operated upon a patient 22 years of age who had been brought up in a blind asylum. He could see to get about, but the presence of a zonal cataract in each eye from infancy did not permit him to see small objects. When the cataracts were removed after he had attained his majority his vision was so far improved that he then learned to to read, and eventually became a successful merchant. It took him nearly two years to acquire a facility to see coarse print, and he never exceeded *pica*, which is the largest type that printers use for the body of many books. No magnifying glass permitted him to recognize fine print. There was a great difference, however, in the amount of sight which these two patients started with. One had only light perception, the other already useful vision and the general recognition of all large objects.

Baltimore, February 2, 1886.

INFLAMMATION OF THE LINING MEMBRANE OF THE FALLOPIAN TUBE, WITH EXUDATION OF PUS OR PUROFIBRINOUS FLUIDS.

BY R. STANSBURY SUTTON, M.D., LL.D.,
OF PITTSBURGH, PA.

This disease is termed salpingitis, and like a bronchitis, it may be acute or chronic. The acute form is not distinguishable from an ordinary peri uterine inflammation. The chronic form may be recognized. In some cases the diagnosis is limited to certain periods in the history of the case, in other cases the symptoms may be so constant as to render it possible to make the diagnosis with considerable accuracy.

The causes of this disease have frequently been said to be limited to gonorrhœal infection. This is an error. It does arise in strumous women from the constant introduction into the uterus of instruments, whether by reason of the introduction of septic matter, or from mechanical violence, I am not sure. But it is more than probable that it arises from the introduction of septic matter. The entire gynecological practice of some seems to be limited to a single procedure, viz. the introduction of the uterine sound, and the *rationale* of the treatment is explained to the patient thus: "There are adhesions between your womb and bladder, or womb and rectum, and these must be broken up." Or "You have got a tumor in your womb, and it will be removed by making pressure on it in this way."

I have just now under my care four striking examples of this treatment persisted in to the production of salpingitis, unilateral, in one; chronic cellulitis and fixation in retroversion of the uterus in another; chronic invalidism in a third; and the fourth case was absolutely free from all disease, but had been gouged regularly for a supposed fibroid which never existed. The constant poking at the interior of a uterus with sounds will frequently produce an inflammatory condition of the lining membrane of the uterus and tubes as well as a general pelvic cellulitis. The older I grow, and the more experience I get, the more am I convinced that local treatment directed to the interior of the uterus instead of to the surrounding structures is entirely too much practised. I find scarcely any use of late years for the old Simpson's sound, sponge or laminaria tents; they lie about as relics of the past. Symptoms are no longer treated for diseases, and the uterine cavity is no longer made a chemical laboratory. The condition of the pelvic and abdominal viscera receives more attention, and less local treatment is required. Tonics, massage, rest, hot water, regulation of the bowels, a good diet, and an occasional application of iodine to the vault of the vagina will soon do away with a host of cases formerly treated with text-book punctiliousness. The cases requiring surgical treatment receive it promptly and with the loss only of enough time to prepare the case. I am sure that such a course is productive of less harm and of more good than the other.

An acute salpingitis recognized as a peri-uterine inflammation should be treated on the well established principles laid down by all authors.

The existence of chronic salpingitis is not always easy of recognition. Mr. Lawson Tait said to me in 1882, at his clinic in Birmingham, England, "Please examine that woman." I did so. He said, "What is that?" I replied "a case of chronic cellulitis." "No," said he, "it is a case of salpingitis, pus in the tubes." I now for the first time knew that I had seen the disease before and had not recognized it. I have seen many cases since, some operated upon by Mr. Tait, and I do not yet feel competent to always recognize the condition. When the symptoms are well marked, and the patient is a married woman or a prostitute, it is easier to recognize it than when the patient is unmarried and above all suspicion—because *sexual intercourse in chronic salpingitis is well nigh unendurable*. Occasionally the muco pus or pus and serum will escape from the tubes through the uterus and relief follows; if the tube fills again the suffering returns. I have seen this occur. Bimanual palpation will reveal a fulness on one or both sides of the pelvis. This fulness or swelling is not solid and painless, but semi elastic and painful. The swelling may be well off on the sides or be directly behind the uterus itself. Other structures than the distended tubes are likely to be involved in the swelling, and if adhesions have formed the mass is fixed.

Pain, reflex in character, is usually complained of in one or both groins, in the back, in the bladder or down the legs. Frequent attacks of pelvic peritonitis occur, lasting eight or ten days. During these the patient cannot walk about without much suffering, and there is an acceleration of pulse and temperature. Pressure bimanually produces a feeling of faintness, and occasionally reflex nervous phenomena approaching hysteria are present. The patients lack color, and bear the evidence in their faces of suffering. One patient often complained of being "so stiff as to be scarcely able to walk." In all of my own cases I have observed that the menstrual flow was disturbed, being profuse and lasting beyond the time, and finishing up with a leucorrhœal discharge sufficient to annoy the patients. In one of them the tube was now and then emptied through the uterus. There was no mistake about this, for I finally removed the tube when it was full of pus. The case was a very interesting one. Twice I postponed operating on account of a subsidence of the mass in the pelvis. The patient insisted that she had for several days observed a flow of matter from the vagina. Finally I was called to see her when she was confined to bed with a severe menorrhagia, and I felt the mass unusually large, tense and painful. As soon as I got her cleared up she entered my private hospital and I operated upon her.

Miss ——— has a strumous constitution, pain in right groin and back, stiffness of thighs, is pale, tongue is heavily furred, is slightly hysterical, has menorrhagia. On local examination, a semi-elastic, painful swelling exists in the pelvis to the right of the uterus. It has come and disappeared, to my personal knowledge, several times in the last six months. In a good light, under Sims's speculum, a little pus is found oozing from the external os uteri. On January 9 she was put on the operating table, etherized by my head nurse, and, Dr. Stone assisting me, I opened her abdomen by a two and a half inch incision, and removed her right ovary and Fallopian tube, the latter full of pus. Her temperature never exceeded 99.5° F. after operation, was normal on the fourth day, and remained so; wound healed, as all my abdominal wounds do, by first intention.

It may be interesting to some to know that no carbolic acid or other chemical touched this patient until the wound was closed, when iodoform gauze was placed over it. The sutures were boiled in clear water, boiling water was poured over the instruments, and boiled water was used for sponges.

MEDICAL PROGRESS.

Exploration of the Uterine Cavity in Cases of Menorrhagia.—At the meeting of the British Gynæcological Society on December 9, Dr. Arthur W. Edis read a paper on this subject. The author desired to draw attention to the urgent necessity of this proceeding, when dealing with cases of severe persistent or recurrent uterine hæmorrhage. The subject was one of great interest, and often one of great anxiety to the practitioner. There was a tendency to treat metrorrhagia as if it were a special disease, in place of regarding it merely as a symptom of many and various conditions A correct diagnosis was the first and most important element of successful treatment, which otherwise was mere guess work Speaking generally, there was almost invariably some local cause when the hæmorrhage was really severe Cardiac, hepatic, or renal disease might be present as a complication, or independently, and should always be taken into consideration Uterine hæmorrhage might be aggravated by the injudicious use of alcoholic stimulants, more especially was this the case about the time of the menopause The author had repeatedly witnessed cases where the mere abstention from alcohol had been sufficient to arrest a profuse hæmorrhage, which had been going on for months, and threatened even the patient's life In attempting to form a rational diagnosis, it was of great importance to get a careful and exact history of the details of the case Before proceeding to local investigation, the heart, lungs, liver, and other organs, should be carefully examined, and inquiry made into the habits of the patient A careful pelvic exploration should follow Then, if after consideration of all the facts of the case, the presumption were, every thing else being excluded, that there was some intra uterine complication, the practitioner was not justified in allowing the patient to go on bleeding indefinitely without giving her the benefit of further assistance The author, in general, effected dilatation by dividing the cervix with the metrotome or scissors, either alone, or in conjunction with the employment of tents or other dilators It was advisable, after operation, to irrigate with some appropriate antiseptic lotion, morning and evening, for a few days In cases of persistent hæmorrhage, due to retention of the placenta, following a miscarriage, the cervix generally remained sufficiently patulous, or was so readily dilatable, that no difficulty was experienced Where, however, only a small portion of the placenta had been retained, and the case allowed to go on for several successive weeks or even months, the cervix might be found so contracted, as to necessitate the introduction of laminaria tents over night In such cases, incision should never be resorted to, this method being reserved exclusively for cases of small fibroid or fibroid polypi in the interior of the uterus The author related several interesting cases to exemplify his meaning, and to show that, until the cavity of the uterus had been explored, a correct opinion could not be formed as to what method of treatment should be adopted He would lay stress upon the importance of dilating the cervix and exploring the interior of the uterus in all cases where hæmorrhage from the organ persisted unnaturally, and where the ordinary medicinal agents failed in affording relief, and there was no evidence of any condition external to the uterus sufficient to explain the persistence of hæmorrhage —Dr Aveling had observed that in cases requiring dilatation where something existed in the uterus capable of being removed, the cervical canal was either dilated or dilatable, this peculiarity had been noticed by Harvey In these cases, he preferred to use his own dilators Where the os was rigid and contracted, a more gradual method was better —Dr Routh believed that Dr Edis's paper was eminently practical, but he took exception to one or two points As to rapid dilatation, of the uterus, it did not always succeed when the uterus was rigid, and after all it was not a rapid, but a long and tedious process requiring an anæsthetic He preferred the sea tangle tents used with proper precautions, and always collected and prepared his own In regard to those cases of metrorrhagia in which nothing could be found after exploration, it should be remembered that an ulcerated or excoriated condition of the mucous membrane need not be restricted to the os or external portion of the cervix, but might extend up the uterine cavity It was quite in keeping to suppose that a congested state of the liver would have the same effect on the uterine mucous membrane as was the case in piles, causing them to bleed and enlarge The last objection he could take was to the incision of the cervix The danger to the patient from septic poisoning was greatly increased by such a measure

Dr Barnes thought no law in therapeutics more clear than that which dictated direct examination of an organ at fault if it could be effected The endeavor to do so was made, in the case of other organs, by percussion and auscultation The uterus offered the incontestable advantage of being directly accessible A narrow condition of the os externum was a frequent factor in cases of hæmorrhage Great benefit was often derived from simply enlarging this opening by a strictly limited incision The immediate effect was to relieve local engorgement It also afforded a ready escape for imprisoned blood-clots and mucus, and gave free access for exploration and the application of topical remedies It was also useful in many cases of intra uterine polypus and fibro myoma of the body of the uterus —Dr Thomas Savage found Hegar's dilators to be very unsatisfactory Laminaria tents were much more efficient, but were sometimes followed by disastrous consequences In several cases in which he had suspected a portion of the ovum to be left behind, he had thoroughly swabbed out the uterine cavity with pure carbolic acid, and found that such a course would often prove sufficient for cure —Dr Bantock was compelled to dissent from Dr Edis on one or two minor matters He did not approve of incising the internal os after partial dilatation, for the purpose of removing a small fibroid tumor, because it would be impossible to control the subsequent extension of the laceration of the divided tissues consequent on the forcible extraction of such a hard body as a fibroid tumor He had met with cases exactly corresponding by those narrated by Dr Edis, and it was quite easy for him to support his views He thought it was a mistake to mix glycerine with iodine or carbolic acid when the full effects of either remedy were desired, for in both instances the caustic effect was in this way reduced to a minimum, if not wholly removed Especially was this the case with carbolic acid He was not prepared to assent to the doctrine that a cervix which was the subject of even extensive disease of a non malignant character, but the result of chronic catarrh, etc , should not be subjected to dilatation These were just the cases in which he obtained the most satisfactory results from dilatation and the subsequent daily introduction of a stripe of lint saturated with glycerine for ten to fourteen days —Mr Lawson Tait considered the use of sponge-tents to be, of all the methods of dilatation, the most dangerous, and had long since given them up Hegar's dilators he considered extremely risky, and their employment was as exhausting for the operator as for the patient —*British Medical Journal*, Jan 16, 1886

Palpation of the Pelvic Organs —Dr B S Schultze, of Jena, has recently published (*Centralbl fur Gynak* , Oct 24), an original communication on bimanual palpation of the pelvic viscera He had already noted ("Ueber Palpation der Becken," *Jen Zeitschr fur Med und Naturw* , 1870, v , p 113) that the contracting and relaxing psoas muscle, along the brim of the pelvis, was an excellent guide to the fingers engaged in detecting the position of the ovary in the bimanual method External pressure along the same part of this muscle will often, in cases of chronic oophoritis, or complicated parametritis, cause severe pain, especially when the hand passes over the ovarian vessels and nerves as they cross over the pelvic brim [*See* reporter's note below, with regard to pressure on the obturator nerve] When the psoas is kept in a state of clonic spasm, through apprehension of pain or through faulty position of the lower extremities, it may readily be taken for a swelling, the result of pelvic inflammation As long as the psoas remains relaxed it cannot readily be distinguished by the hand placed upon the iliac fossa, but the pelvic brim can be felt through it When, however, the patient bends her thigh, the brim cannot be felt through the contracting muscle, which becomes very evident to the touch, and is distinctly tender

Dr Schultze finds that two muscles are to be detected on careful vaginal palpation, and to be taken into account as valuable guides to other structures These are the obturator internus and the pyriformis [The sphincter vaginæ and levator ani are easy to detect The anterior part of the latter, when in active contraction, is often mistaken for the former, which lies below it, separated sometimes by a distinct groove The tendinous arch, whence part of the levator ani takes its origin, can be felt under the lateral part of the vagina, and, by passing the finger forwards towards the anterior bony origin of the muscle, behind the body of the os pubis, the obturator gland can be detected if it be enlarged or inflamed, as in some cases of pelvis cellulitis and gonorrhœa Vaginismus is very frequently, we find, caused by painful contraction of the levatores ani in cases of fissure of the anus or inflamed hæmorrhoids —*Rep*] The obturator internus, Dr Schultze states, is a muscle generally well developed, and its movements can be felt through the vaginal walls if the patient rotate the corresponding leg outwards Its contraction becomes particularly evident during extension and adduction of the thigh, when not only its origin around the obturator foramen can be defined, but also the portion lying further back towards the sciatic notch Pressure on the contracting muscle seldom causes pain, but pressure on the obturator nerve produces sharp crampy pains, radiating to the thigh along the course of the nerve [This, if misunderstood, may be taken to be symptomatic of some acute inflammatory process in the pelvic cavity A thorough exploration of the vagina with the finger, in a case of suspected uterine disease, is very likely to involve pressure on the nerve, and this may become a source of fallacy Pressure on the ovarian plexus must also cause pain even in health, and thus the tenderness is not necessarily a proof (*vide supra*) of chronic oophoritis —*Rep*]

The pyriformis is difficult to detect by vaginal palpation in subjects where the vagina is long, and the pelvis deep It can easily be touched when the pelvis is shallow and the vagina broad, or in women of diminutive proportions When the uterus is high up, as in advanced pregnancy, the finger can easily reach the upper border of the muscle The pyriformis is, according to the evidence of palpation, very irregularly developed in different patients, and it is not so evidently set in action as the obturator, during active rotation outwards of the lower extremity On the other hand, in many cases it remains in continual contraction, especially when the patient lies in an uncomfortable position, or is in a state of alarm Pressure on the contracting pyriformis is often intensely painful, possibly, ("vielleicht," *evidently*, might be said with full confidence —*Rep*) through transmission of the pressure to the sacral plexus Through these peculiarities the pyriformis may become a prominent source of fallacy Dr Schultze, a few years ago, examined a very corpulent patient suffering from chronic metritis and parametritis He took the two contracted pyriformes for the ovaries fixed to the back of the pelvis

When both the pyriformes and the obturatores interni are set in action, the bulging of the obturators is most prominent a little behind the middle point of the foramen ovale As each obturator bulges but little, there is not much chance of its being taken for a tumor or a collection of inflammatory deposit The most projecting part of the pyriformis in full contraction is much more evident to the touch, it stands out three quarters of an inch or more from the anterior surface of the sacrum The inner borders of the two pyriformes in full contraction lie over an inch apart, so that two fingers can be pushed between them in vaginal palpation The separate bands of fibres can be detected as they arise from the sacrum between the sacral nerves, provided that the muscle be set in action whilst the finger presses in the right direction If the patient, lying in an easy attitude, have rotated the lower extremity outwards without setting the pyriformes in action, she should be told to hold the thigh stiff This will set all the femoral muscles in action, and the pyriformes may then be distinctly felt This will be sufficient to distinguish the muscles in question from a morbid growth or deposit —*London Medical Record*, January 15, 1886

Nutrient Suppositories —A case was related by Mr Godlee, for himself and Dr Barlow, at the last meeting of the Clinical Society, in which the advantage to be derived from nutrient suppositories was well exhibited The patient, as will be seen from a perusal of our report of the meeting, suffered from typhlitis Mr Godlee opened the abscess cavity, and allowed a large quantity of fœtid pus to escape The patient eventually quite recovered, without any palpable evidence of the thick bands of inflammatory material which are so troublesome in many cases treated on expectant methods, and had since had no sign in any way of any trouble whatsoever about the cæcum Dr Barlow, speaking of the diatetic treatment after the operation, remarked "that in this case it was especially desirable to keep the stomach and intestinal tract at absolute rest For many days, therefore, the very minimum of food, namely, a little barley-water, was given by the stomach, and the patient was fed by the rectum The thirst was found to be entirely relieved by enemata of three quarters of a pint of water, which were in all cases absorbed With regard to rectal alimentation, it is often observed that after two or three days the rectum becomes intolerant of nutrient enemata To avoid this, food was given in form of digestive suppositories Of these, two very convenient forms were made The first was made by diluting a good meat extract with water, and peptonizing it with Bullock's pepsin, neutralizing, and then concentrating, to a soft paste Cacao butter was then added in fine shavings, and intimately mixed with one-third of its weight of the peptonized meat-extract, and rolled into cones weighing 100 grains The second was made by peptonizing milk with pancreatic solution, boiling and concentrating to a paste, mixing and dividing as in the first case Peptonized milk being now sold in a concentrated form, it may be used instead of ordinary milk, which saves much time and trouble The suppositories were certainly absorbed, and kept the patient going for several days One was introduced about every three hours His tongue became very dry, after a time he was given some pieces of underdone chop, which he was allowed to chew and to swallow the juice derived therefrom, but not the fibre Besides maintaining his nutrition fairly, the patient, who was rather an irritable, querulous subject, was satisfied and comfortable, and the advantage in keeping his abdomen quite quiescent was very great indeed" If other cases should confirm the favorable impression as to the advantages to be derived from this method of feeding, when contrasted with the failure which in a few days generally results from the attempt to sustain life by nutrient enemata, as the rectum generally soon becomes intolerant of them, there will doubtless be found a wide use for these suppositories in the very large class of cases in which the stomach requires to be kept at rest Those who employ them may find, too, that the liquid which the system requires daily may be in some cases administered by the stomach, this would, one might suppose, tend still less to the disturbance of the lower bowel, and leave it still more at rest to digest and absorb the suppositories alone —*British Medical Journal*, December 19, 1885

TRANSPLANTATION OF BONE —DR FERRARI, (*El Siglo Medico*, Nov 22, 1885,) arrives at the following conclusions 1 Pieces of bone inserted in the diaphyses of long bones may become completely united to them, and continue to live 2 They not only continue to live, but also grow 3 The insertion of bone gives results in whatever position the piece of bone is applied 4 The re-union or grafting takes place by a true vascularisation, which forms between the piece inserted and that to which it is applied 5 Around the piece inserted, a bony, periosteal, and medullary callus is formed 6 As in a fracture, this callus has only a temporary vitality 7 After the lapse of a certain time, the periosteal and medullary callus is reabsorbed, and the engrafted bone is only to be recognized by its greater vascularity 8 The grafting takes place whether the piece inserted be completely adapted to the margin of the wounded bone or not, but in the latter case a longer time is required for union 9 For successful insertion a rigorous antisepsis is necessary 10 A favorable result is obtained even when the smallest pieces are inserted 11 In the case of insertion of small pieces of bone, if partial suppuration of the wound occur, some small pieces may yet adhere if the suppuration do not extend to the parts of the bone inserted which touch the medulla 12 For the complete success of the insertion, apart from antiseptic medication, moderate pressure must be employed to maintain contact between the medulla and the piece of bone transplanted —*London Medical Record*, January 15, 1886

ALBUMINOMETRY AND ESLACH'S TUBES —MR J A BLOMFIELD says that the usual method for the quantitative determination of albumen in the urine in the course of clinical work must be regarded as unsatisfactory It consists generally in boiling a test-tube about half filled with the urine, allowing the coagulated albumen to subside, and then getting by sight a rough estimate of the proportion of the albumen to the amount of urine employed There is a method used in many of the French hospitals which yields results possessed of numeric accuracy, and which serves to give a good idea of the actual amount of albumen in the urine The method was devised by Dr Esbach, and consists in the precipitation of the albumen by means of picric acid After standing twenty four hours, the precipitated albumen reaches a certain height in the tube, and it is according to height to which it reaches that the amount of albumen is determined The tube is empirically graduated in such a way that the number to which the precipitate reaches gives directly the grammes of albumen per litre of urine The reagent for precipitation is made by dissolving 10 grammes of picric acid and 20 grammes of citric acid in 800 or 900 c c of boiling water, and then adding sufficient water to make one litre Urine is poured into the test-tube up to a certain mark, the reagent added up to another mark, and then the tube is inverted about a dozen times to mingle well the contents, and placed in the vertical position for twenty-four hours, when the height to which the subsided precipitate has reached gives the grammes of albumen per litre —*The Lancet*, Jan 23, 1886

THE

Journal of the American Medical Association

PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address, although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES 10 CENTS.

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address,

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 65 RANDOLPH STREET,
CHICAGO, ILLINOIS.

SATURDAY, FEBRUARY 13, 1886.

"OPERATIVE SURGERY OF THE BRAIN."

Such is the title of a most exhaustive paper read by DR. JOHN B. ROBERTS, of Philadelphia, before the last meeting of the American Surgical Association. The paper, which has been printed in book form, makes an octavo volume of eighty pages, and is divided into three chapters, which deal respectively with the "Principles of Cerebral Surgery," "Cerebral Localization," and the "Operative Treatment of Cerebral Lesions."

The consideration of the principles of cerebral surgery is taken up under a number of propositions, the first of which is that "the complexus of symptoms called 'compression of the brain,' is due not so much to displacing pressure exerted on the brain substance as it is to some form or degree of intracranial inflammation." We must agree with the author that too much has been made of "compression of the brain," and to a great extent with Hutchinson in saying that "compression of the brain from depressed fragments of bone is an imaginary condition." Dr. Roberts thinks that it would be well if traumatic "compression of the brain" were always translated "inflammation of the brain," and if the profession were taught to believe that it was due to irritation of the periphery of the brain from traumatic causes. The second proposition is that "The conversion of a closed (simple) fracture of the cranium into an open (compound) fracture by incision of the scalp is, with the improved methods of treating wounds, attended with very little risk of life." It must surely be admitted that so long as the cranial fracture is closed the surgeon must be to a great extent in the dark as to its precise character, and it is in this respect that a simple fracture of the cranium differs from every other fracture. "Uncertainty as to the character of a cranial lesion is more dangerous to health and life than the conversion of a closed into an open fracture of the skull, because observation has taught the profession that open cranial fractures do not resemble in fatality similar open fractures of long bones." This argument finds strong support in the fourth proposition, that in the majority of cranial fractures the inner table is more extensively shattered and splintered than the outer. The question, then, resolves itself into one of correct diagnosis. We must learn the character of the lesion, and then we are in a position to apply the surgical expedients necessary, and since the day of antiseptic surgery restoration to health is more probable than improbable even with the complication due to the incision.

The third proposition is that "The removal of portions of the cranium by the trephine or other cutting is, if properly done, attended with but little more risk to life than amputation of a finger through the metacarpal bone." Of the 115 cases of trephining collected by Amidon there were only four deaths which could be attributed to the operation. Dr. Briggs has probably performed the operation as often as any man in America, and it is his opinion that it is one of the safest of the capital operations. The risk would be still further diminished, probably, if surgeons were to confine themselves to the conical trephine or the burr of the dental engine, and throw away the mallet and chisel. We have already said that the fourth proposition is that the inner table is usually more extensively shattered and splintered than the outer table. This has been shown by experimental fractures produced in the dissecting room and by observation of cases in private practice, and it is simply in accordance with a well-known mechanical law. It is easily seen, then, that the great danger is from inflammation set up by the depressed fragments of bone, and not from compression. As regards the fifth proposition, that "perforation of the cranium is to be adopted as an exploratory measure almost as often as it is demanded for therapeutic reasons," there must necessarily be much difference of opinion, but as in the case of laparotomy for diagnosis if the surgeon cannot see his way without perforating the cranium the surgical reasons seem to be on the side of exploration. The risks of obscure knowledge are usually greater than those of divided scalp and perforated bone, and the earlier the exploration the less the risks. Comment upon the sixth proposition, that "Drainage is more essential in wounds of the brain than in wounds of other structures," seem scarcely necessary, since, in view of recent papers and cases, the proposition seems almost self-evident, as does the seventh that "Many regions of the cerebral hemispheres of man may be incised with comparative impunity." We are sure also that those who have read the reports of the cases of Bull, Parkes, Hopkins Sands, Brinton and Nancrede will agree that "Accidental or operative injuries to the cerebral membranes, meningeal arteries or venous sinuses, should be treated as are similar lesions of similar structures in other localities." And as regards the ninth and last proposition, that "The results of cerebral localization are more necessary to the conscientious surgeon than to the neurologist," very little consideration will show that it is true, and that as a rule surgeons do not pay sufficient attention to the subject. When the neurologist is wanted to give an opinion in the matter the necessity is not so pressing that one or two days will make much difference, but with the surgeon the opinion must be formed immediately. An operation is or is not necessary, and if necessary it should be done at once. And for those who desire to make a study of this subject, we do not know where a better account of it can be found than in the second chapter of the valuable monograph under consideration.

Passing over the second chapter, which deals exclusively with cerebral localization and contains tables of "indications in traumatic cases," of "contra-indications," of "points for opening the cranium when operation is indicated," and of "more uncertain localizations," we may now consider the third chapter—"Operative Treatment of Cerebral Lesions"—in which the principles laid down in the first chapter are applied to the treatment of (a) cranial fractures, (b) intracranial hæmorrhage, (c) intracranial suppuration, (d) epilepsy and (e) insanity following cranial injury, and (f) cerebral tumor. In discussing the treatment of cranial fractures Dr. Roberts asks four questions: 1. What conditions demand incision of the scalp? 2. What conditions render incision of the scalp unjustifiable? 3. What conditions demand perforation of the skull? 4. What conditions render perforation unjustifiable? These questions are answered in a tabulated statement. In cases of *closed fissured fractures* he would not operate if there be no evident depression and no brain symptoms, but he would incise the scalp and trephine with brain symptoms with or without evident depression. With evident depression and no brain symptoms he would incise the scalp and possibly trephine. He would be inclined to trephine if the depression was marked, or the fissures sufficiently multiple to approach the character of a comminuted fracture. In cases of *closed comminuted fractures* he would trephine with evident depression with or without brain symptoms, and with brain symptoms without evident depression. With no evident depression and no brain symptoms he would incise and probably trephine. (He would trephine unless the comminution was inconsiderable.)

With *open fissured fractures* he would trephine with brain symptoms with or without evident depression, with neither evident depression nor brain symptoms no operation should be performed, while with evident depression and no brain symptoms he would possibly trephine. (He would be inclined to trephine if the depression was marked, or the fissures sufficiently multiple to approach the character of a comminuted fracture.) In cases of *open comminuted fractures* he would trephine except when there is neither evident depression nor brain symptoms, when the operation would be performed unless the comminution was inconsiderable. Punctured and gunshot fractures always demand operation. It should be remembered that when operations for fractures of the skull are demanded they should be performed immediately or within a few hours. The risk to life is enormously increased by waiting to see if the patient may not get along very well without an operation. But whether the operation be performed or not all cases, says Dr. Roberts, should be treated as cases of incipient inflammation of the brain (meninges?).

When is perforation of the skull, in order to remove a clot and secure bleeding vessels, justifiable? An operation says our author, is contra-indicated in cases of intracranial bleeding that do not present the symptoms which are believed to be produced by accumulation of blood in either the cavity of the arachnoid or the space between the skull and the dura mater. If localized hæmorrhage within the arachnoid be reasonably ascertained, he considers trephining justifiable. When the disc of bone has been removed the bluish and non pulsatile dura will probably bulge into the opening, and should be incised to allow the blood to escape. In some cases, however, this bulging will not occur until many hours after the injury. Gradually increasing brain symptoms, after injury to the head, "especially if there has been a period of return to consciousness after shock of traumatism, suggest the occurrence of intracranial bleeding from meningeal vessels," even should no fracture or depression of bone be detected. Operation is especially indicated if the localizing symptoms point to no other region of the cortex and if the symptoms are such as render cerebral laceration improbable. "A very short interval of immunity (from head symptoms after traumatism) indicates rapidly flowing hæmorrhage and demands early operation, with probable ligation of the middle meningeal artery or one of its large branches, or ligation or compression of a sinus It must be remembered also that compression symptoms, coming on immediately or quite soon after depressed cranial fracture, are very often due to the subcranial clot rather than the depressed cone Removal or elevation of bone is often needed more for liberation of blood-clot and control of hæmorrhage than for deformity in the bony outline"

Mr Charters Symonds reported a very interesting case of laceration of the middle meningeal artery before the Clinical Society of London, on October 9 The patient fell on his head, and soon became completely insensible Mr Symonds trephined on account of hemiplegia and deepening coma A pulsating clot was removed, and hæmorrhage was profuse In order to reach the laceration a great deal of bone was removed Two lacerations of the vessel were found, one of which was closed by over-running the vessel with fine gut, and the other by dividing the vessel and twisting both ends Hæmorrhage still continued, and was arrested after the bone had been incised to the base, by under running the artery with a piece of dura mater, making traction on the ligature carried out of the wound, and by carrying a pair of torsion forceps down as far as possible and giving half a twist The patient died fifty hours after the accident, but death could not be attributed to the operation

Of the treatment of intracranial suppuration we can only say that if the surgeon can locate the seat of suppuration he should operate and evacuate the pus, if he cannot locate it he should hunt for it, taking care that the aspirating needle be not thrust too deeply towards the medulla and base of the brain The case reported by Nancrede to the American Surgical Association, in 1884, shows that it is never to late to seek for pus Of Dr Robert's remarks on trephining for epilepsy, insanity and cerebral tumors want of space prevents our saying anything We set out with the intention of calling attention to the more noticeable features of his exceedingly valuable and masterly monograph, and have exceeded our limits He is to be congratulated that he has been able to compress so much information, and so much good surgical reasoning into so small a book—for it is one to be studied, and studied hard by every-one who may possibly have to deal with an injury of the skull or brain, and we must regard the operation as both justifiable and demanded

HYPODERMATIC MEDICATION

It is thirty years since Dr Alexander Wood, of Edinburgh, introduced to the medical profession the subcutaneous method of administering remedies The entire following of Æsculapius may be said to be armed with hypodermic syringes Yet it is doubtful if the average practitioner, as a rule, uses this instrument for the administration of anything except morphine Again, it is probably safe to assume that too great recklessness is often shown in the use of this mode of giving this remedy It is not always easy to substantiate the suspicion that a patient has succumbed to an overdose of morphine thrown under the skin, whereas it is a very easy thing to entertain and even express such a suspicion This is shown by the frequency with which the laity whispers the account of some case in which Dr ——— gave Mrs ——— a dose of morphine hypodermatically, when she went into a heavy sleep and never awoke Doubtless many of such instances are examples of *post hoc, propter hoc* Yet it is only too true that some of the patients thus treated have been sacrificed However exceptional death from the subcutaneous administration of morphine may be the mere fact that such an untoward result is possible should lead physicians to err, if err they must, on the side of caution

The subject of "Hypodermic or Subcutaneous Medication" was discussed at the fifty-third annual meeting of the British Medical Association, at Cardiff, last year As the two questions, concerning the range of its employment and the extremes of the doses regarded as safe, were considered, it may be well to give the readers of THE JOURNAL a summary of the ideas there presented The discussion was opened by Dr Talfourd Jones in the Section of Pharmacology and Therapeutics He would not limit hypodermatic medication to morphine by any means, but would recommend all practitioners to carry appropriate solutions of atropine, apomorphine, and a combined solution of morphia and atropine in the proportion of twenty to one There can be no doubt that given subcutaneously, morphine acts more promptly, certainly, and with fewer disagreeable after-effects than by the stomach Moreover, its effect is not merely a general one, but in addition it exerts a local anodyne power, which is marked and often of great service

In this respect Talfourd Jones is a disciple of Alexander Wood, not of Hunter He believes that in curing neuralgiæ, such as sciatica, brachialgia, trigeminal neuralgia, etc, it is far more efficacious to inject the narcotic at or near the seat of pain than at some remote part. He cites cases in support of this position of which space forbids the repetition here. He is of the opinion that there should be a definite and uniform dosage established for this powerful agent. Lawson thought the initial dose should be $\frac{1}{6}$ of a grain, but Jones has seen very alarming effects follow that amount. There are many conditions that must govern the size of the dose in each individual case, such as the bodily weight, the age, idiosyncrasy, and the intensity of the pain or gravity of the condition which calls for the hypodermatic use of the remedy. He would suggest that for an adult female the initial dose of morphine by this method should be $\frac{1}{10}$ gr., while for a grown male $\frac{1}{8}$ might be employed. He would never give morphine subcutaneously to children, if possible to avoid it, while to one under the age of 5 years it is never admissible.

Jones employs and earnestly recommends a solution of the acetate of definite known strength. For sixteen years he has used a solution always made in the same way and of the same strength. The salt used should be fresh. "Procure a stoppered bottle that holds exactly one fluid ounce. Half fill this with water, which I never use distilled, then put into the bottle 40 grains of acetate of morphine and drop into it exactly 4 minims of acetic acid. Shake and the salt will instantly dissolve. Then fill the bottle with water. The resulting solution will be pale and clear. Such a solution, if properly kept, will not in six months throw down more than a fraction of a grain of the acetate. It will perhaps become darker in color, but this is immaterial." It should be kept away from the light. It is much stronger than the solutions commonly employed in this country, 12 minims representing 1 grain of the drug. Great care has to be taken in the measurement of so strong a solution, and unless syringes are used the pistons of which are provided with a nut, there would seem to be a greater likelihood of accidents. Moreover, the acetate is said to contain 10 per cent. more morphine than does the sulphate.

The reader next considered atropia. He advised its employment hypodermatically often because of its unrivaled power over muscular spasm, as in hepatic, renal and intestinal colic. It is used as an anodyne and antispasmodic, as an anhydrotic, as a respiratory and cardiac stimulant and as an antidote to opium narcosis. He advised a solution of the strength of 2 grains to the ounce of water, and of this the dose is from 1 to 6 minims. Having considered and recommended these remedies separately, he yet desired to endorse most emphatically their combined administration in the proportion of 1 to 20. Indeed, he rarely employs morphine alone, except in certain cases in which it is desirable to lessen the vigor of the respiration. In painful thoracic diseases, as pleurisy, it is well to leave out the atropine, since its stimulation of the respiratory act would be likely to aggravate the suffering.

In other cases he would use the combined solution, on account of its certainly modifying the unpleasant after effects of morphine. Before leaving the subject of these agents he would emphatically recommend the hypodermatic use of moderate doses of this "atropho morphine," as he dubbed their combined solution, in attacks of cardiac asthma. These attacks, which are paroxysmal and occur chiefly at night, are most quickly and beautifully relieved by this means. The effect is to stimulate and not depress the already weakened and overburdened heart. This is no new idea, yet it is so certain and valuable an addition to a practitioner's therapeutic knowledge that we are glad to have Talfourd Jones give it his endorsement.

Lastly, he would urge the hypodermatic use of apomorphine. It is a prompt and safe emetic, specially serviceable in cases of poisoning and alcoholic intoxication. A convenient solution of the hydrochlorate can be made of the strength of one per cent., and of this the dose for an adult should be from 4 to 10 minims, that is, from the twenty-fifth to the tenth of a grain. The $\frac{1}{20}$ will produce emesis in from three to five minutes. For children 1 to 2½ minims should be employed. Still, he thinks it preferable to administer it to young children by the stomach. It should be remembered, however, that apomorphine acts very slowly when given in this way, since its action must depend upon its being absorbed.

As regards the needles employed, Jones is of the opinion that they are best made of steel, since they penetrate more easily and with less pain than those made of silver. Except when intended to reach deep tissues, their length should be from three-fourths of an inch to one inch. Such needles are easily cleaned and not likely to bend or break. Other practical points touched upon it is not best to mention here, as they are such as would naturally suggest themselves to any practical man.

In conclusion it may be said that there are several other remedies, such as pilocarpine, which are usefully given subcutaneously, and which it is advisable to have at hand. German therapeutists are very fond of administering the bichloride of mercury hypodermatically for the treatment of syphilis. This method was introduced by Lewin, and is very efficacious when it is desirable to bring the system rapidly under the influence of the drug The dose is from 1/6 to the 1/8 of a grain It is combined with 1/10 grain of morphine, and a small amount of sodium chloride, dissolved in 15 minims of water and injected beneath the skin of the back This mode of treatment has the endorsement of high authority Hypodermatic medication possesses many advantages and ought to receive greater attention on the part of the general practitioner

It is somewhat remarkable that so few physicians heat the solution for subcutaneous injection The amount to be injected may be put into a teaspoon, and a lighted match held under it until it boils By the time the fluid is taken into the syringe and the needle screwed on it will usually be sufficiently cooled to inject We are confident that many cases of abscess and sore arm would be avoided by taking this little trouble, especially when the more irritating preparations are used And when the solution is made on the spot boiling the water ensures solubility, and often precludes the necessity of the addition of an acid as a solvent It is often the case that nervous patients will contract the muscles of the arm into which the injection is to be made, and the injection is thus often made into a muscle This may cause an abscess Lastly, injections should be made, if possible, in a region comparatively free from superficial blood-vessels, and where there is a large amount of areolar tissue

TREATMENT OF CARBUNCLE WITHOUT INCISIONS

At the annual meeting of the American Medical Association, in May, 1885, Dr L D Bulkley, of New York, read a paper claiming a good degree of success in the treatment of carbuncles of all grades of severity, without incisions or other surgical procedures His method consists essentially in the daily dressing of the carbuncle with unirritating and somewhat antiseptic unguents spread on thick soft felt cloth, and the giving of sulphide of calcium internally, and proper diet In the discussion which followed several of the more experienced members of the Section coincided with Dr Bulkley

It was stated by the writer of the paper that free incisions through the diseased structures, by severing blood-vessels, added to the danger of septic poisoning, and thereby doing in some cases positive harm Since the publication of Dr Bulkley's paper in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for May 16, 1885, an article has appeared in *Daniel's Texas Medical Journal*, of November, 1885, by DR C H WILKINSON, of Galveston, giving the results of his experience in the treatment of carbuncles with injections of carbolic acid during the last six or eight years He fully sustains Dr Bulkley in the opinion that surgical interferences with carbuncles are worse than useless We cannot give a better idea of the plan of treatment which Dr Wilkinson claims to be original with himself, than by copying the following paragraphs from his paper

"An Italian laborer, æt 51, applied to me for treatment of a well developed carbuncle situated upon the posterior cervical region, which measured five by six inches and was very irritable I selected two or three of the most prominent sinuses and injected into each of them about 10 minims of pure carbolic acid, full strength On the second day after the injection it was noticed that the inflamed areola had nearly disappeared, and the sore itself was casting off several large sloughs A few more drops of acid were then injected, after which the ill-conditioned, painful and highly inflamed carbuncle was converted into a simple, healthy, granulating ulcer, which healed to complete recovery within a few weeks after Since the treatment of this patient I have fallen heir to many similar cases, the carbuncle in the great majority of instances being situated on the nucha, and in every instance did a speedy return to health follow the carbolic acid treatment, as carried out in the case of the Italian My method of employing the agent has been, as just stated, to select a few prominent sinuses and inject into them from five to ten drops of pure liquid carbolic acid, using an ordinary hypodermic, or, better still, a Heaton's hernia syringe, throwing the fluid in the direction of the hard, red and painful spots about the periphery, and being careful to pick up all excess of acid that might ooze back through neighboring sinuses, with sponge or blotting paper

"Carbolic acid in this class of cases acts by converting an unhealthy into a healthy inflammation All erysipelatous tendency is checked instanter, wherever the acid touches, while the stimulus it affords to the capillaries promotes absorbtion on the one hand and healthy granulation on the other Great sloughs of necrotic, connective tissue are thrown off, and the carbuncle is soon converted into a rapidly-healing simple ulcer Furthermore, carbolic acid acts as a local anæsthetic in these cases, and did it do no other good than this in these most painful affections we would be amply justified in its employment for this purpose alone "

The plan here suggested is certainly worthy of a fair trial, with proper caution, lest too much of the carbolic acid might enter the circulation

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, February 1st, 1886.

THE PRESIDENT, C. T. PARKES, M. D., IN THE CHAIR.

DR. J. SUYDAM KNOX read a paper entitled

QUINSY AS A RHEUMATISM.

The author reported the treatment of fifty cases of the disease. In forty five cases (95 per cent.) there was a positive rheumatic diathesis. Forty of these cases were cured in thirty-six to seventy-two hours, without suppuration. The treatment was salicylate of sodium, and hot alkaline gargles, or the repeated insufflation on the tonsils of bicarbonate of soda. Five cases, decidedly rheumatic, were not benefited by similar treatment. Five cases, not rheumatic, were not benefited, and at the end of forty-eight hours the ordinary treatment of quinsy was followed. Only one of these cases did not suppurate. The doctor concludes that a large majority of quinsies are rheumatic inflammations. 1. From the percentage observed. 2. From the success of anti rheumatic treatment. 3. From the similarity between the symptoms of quinsy and rheumatism.

Dr. Knox said that wherever possible he used an insufflator and blew bicarbonate of soda directly on the tonsils, using as much as 30 grains, and allowing it to remain on the tonsils as long as possible, to be followed by a gargle of water as hot as could be borne and to be continued until the throat was cleared, which would take from half an hour to two hours. He sometimes used carbolized lime water, with morphia. He said that he could not say as to every case, but that where suppuration takes place it is usually in the gland, an abscess is formed from glandular inflammation and suppuration takes place through the gland.

DR. A. B. STRONG reported

A CASE OF INTUBATION OF THE LARYNX FOR ACUTE CATARRHAL LARYNGITIS, WITH RECOVERY.

He said the patient was a child, æt. 2½ years, delicate and small for her age. She had been sick thirty-six hours when it was decided that intubation was imperatively demanded, and it was done. Instant relief was obtained. The act of introducing a No. 3 tube had caused such an abundant ejection of the mucus, and the breathing was so easy, that the tube was withdrawn, and the child passed the night comfortably. However, at 4 P. M. of the succeeding day the tube was re-introduced with the same success, but about twelve hours after the child caught hold of the thread and withdrew the tube. The No. 2 tube was then placed in position and remained there sixty-eight hours, when recovery was complete. Dr. Strong said intubing the larynx has advantages over tracheotomy in being quickly performed, furnishing instant relief without cutting or bloodshed, being free from danger, and readily assented to by the parents. The care of the patient after operation is slight, as compared with tracheotomy, as the tube does not have to be interfered with, nor does it often clog up. The tubes as now made, those of Dr. O'Dwyer, are not easily coughed up. It is easier to introduce than remove the tube, owing to the fact that if the thread is left in the mouth it causes coughing and difficulty in swallowing. It was observed that during the thirteen hours the child wore the tube with the thread she had more difficulty in swallowing than subsequently when the thread was withdrawn, the thread being drawn across the epiglottis probably interferes with it closing the glottis during deglutition. Besides, the thread requires constant watching lest the child grasp it and withdraw the tube. Still, in case a mass of mucus should lodge against the lower end of the tube and stop respiration, the thread might be the means of saving the child's life by allowing the tube to be speedily withdrawn.

THE PRESIDENT said it was a matter of surprise to him that so small an opening would allow the exit of secretions, as in the case just reported. It had been his experience that recovery always follows cases of catarrhal laryngitis. However, in these cases, he thought the introduction of the tube might be of great benefit in relieving difficult breathing or dyspnœa, and in allaying the fears of friends. He was aware that a very small opening gave air sufficient for inspiration for some hours. He once operated on a boy about 5 years old, in whom the trachea by improper manipulation was turned in some way, and the incision made in the side of the trachea. When the external tracheotomy tube was introduced into the wound the child breathed quite well, the suffusion of the face passed away and the lips became red, but still the sound of the breathing was not satisfactory to the ear. He then tried to introduce the internal tube and found the child had a return of all the symptoms of suffocation. On removing the external tube at the bottom of the wound the trachea was seen unopened. The child recovered. The President said that while the tube was in this bad position he looked into it through the fenestra, and the bottom of the fenestra was an opening through which the smallest probe could be introduced into the trachea, which enabled the child to inspire air enough to relieve the urgent symptoms. He thought that in a case of true diphtheritic laryngitis an opening of the size of the tube under discussion could, in his opinion, not give exit to any such amount of secretion as is frequently seen during an operation. He did not think that intubation of the larynx would take the place of tracheotomy, it no doubt is of great benefit in those cases where the patient is likely to die unless some measure be quickly adopted which will give time enough to allow the operation of tracheotomy. In the case under discussion the tube was worn sixty eight hours continuously. He had not seen a case of tracheotomy where the closure of the fenestra gave evidence that the trouble with the larynx or glottis was overcome in less than six days. This was the shortest time in which he had been able to remove the tracheotomy tube.

DR. F. E. WAXHAM said that from his experience with intubation of the larynx he was thoroughly convinced of its utility, and its superiority over tracheotomy He had eight recoveries out of his first seventeen cases, a result which he claimed could not be approached by tracheotomy, especially in Chicago The ages of the patients varied from 11 months to 5 years, he considered these eight cases as being saved from certain death, as in only one case would tracheotomy have been permitted by the friends, and he had the corroborative evidence of other physicians as to the impending danger, and the urgent necessity of surgical interference Since his last report he had had a number of cases, and had performed the operation four times during the last week, one patient being only 11 months old, suffering from both laryngeal and pharyngeal diphtheria, the urgent symptoms were at once relieved In another case aged 18 months, where death was impending, the tube was introduced without difficulty and the child relieved, and recovery would without doubt have been the result had not the child died of pneumonia on the second day In another case, one of malignant diphtheria in a child of 2 years, the patient succumbed on the second day after the operation In another case he found the patient cold and livid, pulseless, and unconscious After the tube was introduced cold water was dashed on the child's face, and in about five minutes he looked around and asked for his father, took some milk and passed into a quiet sleep This child died from pneumonia three hours later Dr Waxham said that in the eight cases that recovered, in every instance false membrane was observed, when the tube was introduced the membrane was ejected, either in large flakes or broken down masses He recommended that in treatment after intubation nothing at all irritating should be given, as when a child takes fluid of any kind a few drops will trickle into the trachea and cause violent coughing, and this irritation will often lead to pneumonia In a child rugged and strong, bichromide of mercury may be given to hasten disintegration of false membrane The most remarkable case coming under his observation was a child of 4 years upon the verge of suffocation, when, upon the tube being introduced, a considerable portion of false membrane was thrown out through the tube and the violent symptoms subsided at once The thread was removed, and the second day after the operation the child was playing about the room and continued about the house during the four days that the tube was worn, and finally made an entire and perfect recovery Dr Waxham thought that in regard to the comparative value of tracheotomy and intubation very much might be said The text-books give as the percentage of recoveries from tracheotomy about one in three, but these statistics are made up from the most favorable reports If a physician has one recovery out of three or four cases he is justly proud of it and reports the case, on the other hand, if there is one recovery out of fifteen or twenty cases, no report is made He had known one physician to have operated fifty times with but two recoveries Dr Waxham thought that the thread should always be removed, as it is a constant cause of irritation, and that no difficulty need be experienced in removing the tube with extractors He thought intubation had a grand future

Dr E Fletcher Ingals did not take an enthusiastic view of intubation excepting for young children, when he thought it would be found more satisfactory than tracheotomy In very young children tracheotomy does not result well, and he thought intubation would be unsatisfactory in older ones until we have larger tubes He stated the accepted opinion of surgeons to be that a tube of less than one-fourth of an inch in diameter can not furnish sufficient air for a child to live on Dr Ingals thought that Dr Waxham had been remarkably successful with intubation, and had demonstrated its utility, for which he deserved credit Dr Ingals thought that intubation of the larynx is preferable to tracheotomy in children less than three and a half years of age, children much older than this cannot get a sufficient amount of air through the tube now in use He said, also, that in performing one operation he had had trouble with the gag, which was not large enough for the child, a boy of five years, who lifted his teeth from the gag and closed them on the doctor's finger He thought there was no need of the thread remaining, as there could be little difficulty in removing the tube Dr Ingals thought in cases where it is difficult to get the consent of friends, or where the conditions are such that tracheotomy cannot be performed right away, intubation would be of value, there are cases not membranous in which intubation may be of value The statistics looked pretty bad for tracheotomy but he had seen statistics of fifteen or sixteen cases where half of them were recoveries His success had not been quite so good, but he attributed this mainly to the fact that he had operated on five children who were almost dead, or at least had stopped breathing before the operation began He had the good fortune once to save a child who had not breathed for what seemed to him twenty minutes One of the strong points in favor of intubation is that it may be done early, and it does no harm even if unnecessary

Dr H T Byford said there was another way of drawing the line which would more accurately describe the usefulness of the two operations Intubation seemed to him the operation for private practice, and statistics so far are comparatively favorable to it as such But the cooperation of the patient's friends, the preparation of the inspired air by passage through natural channels, the freedom of intubation from grave responsibility, its bloodlessness, the simplicity of treatment afterwards, as well as the greater rapidity with which the mucous membrane around the vocal chords will get well, are conditions which have less bearing in hospital practice, where we have trained nurses and all modern appliances, and there is more hope of success in tracheotomy While he did not think this latter operation favorable for private practice, such advantages as having the tube under the eye, and within reach of the fingers, of an attendant, the ease of local medication, the possibility of removing shreds of membrane and plugs of mucus, and of inspecting the parts by removing the tube, and the longer time the tube can be retained, these are things that do not pertain to intubation, and which, in hospital practice, must secure for it some consideration He said that there was one

THE PRESIDENT, C T PARKES, M D , IN THE CHAIR

DR J SUYDAM KNOX read a paper entitled

QUINSY AS A RHEUMATISM

The author reported the treatment of fifty cases of the disease In forty five cases (95 per cent) there was a positive rheumatic diathesis Forty of these cases were cured in thirty-six to seventy-two hours, without suppuration The treatment was salicylate of sodium, and hot alkaline gargles, or the repeated insufflation on the tonsils of bicarbonate of soda Five cases, decidedly rheumatic, were not benefited by similar treatment Five cases, not rheumatic, were not benefited, and at the end of forty-eight hours the ordinary treatment of quinsy was followed Only one of these cases did not suppurate The doctor concludes that a large majority of quinsies are rheumatic inflammations 1 From the percentage observed 2 From the success of anti-rheumatic treatment 3 From the similarity between the symptoms of quinsy and rheumatism

Dr Knox said that wherever possible he used an insufflator and blew bicarbonate of soda directly on the tonsils, using as much as 30 grains, and allowing it to remain on the tonsils as long as possible, to be followed by a gargle of water as hot as could be borne and to be continued until the throat was cleared, which would take from half an hour to two hours He sometimes used carbolized lime water, with morphia He said that he could not say as to every case, but that where suppuration takes place it is usually in the gland, an abscess is formed from glandular inflammation and suppuration takes place through the gland

DR A B STRONG reported

A CASE OF INTUBATION OF THE LARYNX FOR ACUTE CATARRHAL LARYNGITIS, WITH RECOVERY

He said the patient was a child, æt 2½ years, delicate and small for her age She had been sick thirty-six hours when it was decided that intubation was imperatively demanded, and it was done Instant relief was obtained The act of introducing a No 3 tube had caused such an abundant ejection of the mucus, and the breathing was so easy, that the tube was withdrawn, and the child passed the night comfortably However, at 4 P M of the succeeding day the tube was re-introduced with the same success, but about twelve hours after the child caught hold of the thread and withdrew the tube The No 2 tube was then placed in position and remained there sixty-eight hours, when recovery was complete Dr Strong said intubing the larynx has advantages over tracheotomy in being quickly performed, furnishing instant relief without cutting or bloodshed, being free from danger, and readily assented to by the parents The care of the patient after operation is slight, as compared with tracheotomy, as the tube does not have to be interfered with, nor does it often clog up The tubes as now made, those of Dr O'Dwyer, are not easily coughed up It is easier to introduce than remove the tube, owing to the fact that if the thread is left in the mouth it causes coughing and difficulty in swallowing It was observed that during the thirteen hours the child wore the tube with the thread she had more difficulty in swallowing than subsequently when the thread was withdrawn, the thread being drawn across the epiglottis probably interferes with it closing the glottis during deglutition Besides, the thread requires constant watching lest the child grasp it and withdraw the tube Still, in case a mass of mucus should lodge against the lower end of the tube and stop respiration, the thread might be the means of saving the child's life by allowing the tube to be speedily withdrawn

THE PRESIDENT said it was a matter of surprise to him that so small an opening would allow the exit of secretions, as in the case just reported It had been his experience that recovery always follows cases of catarrhal laryngitis However, in these cases, he thought the introduction of the tube might be of great benefit in relieving difficult breathing or dyspnœa, and in allaying the fears of friends He was aware that a very small opening gave air sufficient for inspiration for some hours He once operated on a boy about 5 years old, in whom the trachea by improper manipulation was turned in some way, and the incision made in the side of the trachea When the external tracheotomy tube was introduced into the wound the child breathed quite well, the suffusion of the face passed away and the lips became red, but still the sound of the breathing was not satisfactory to the ear He then tried to introduce the internal tube and found the child had a return of all the symptoms of suffocation On removing the external tube at the bottom of the wound the trachea was seen unopened The child recovered The President said that while the tube was in this bad position he looked into it through the fenestra, and the bottom of the fenestra was an opening through which the smallest probe could be introduced into the trachea, which enabled the child to inspire air enough to relieve the urgent symptoms He thought that in a case of true diphtheritic laryngitis an opening of the size of the tube under discussion could, in his opinion, not give exit to any such amount of secretion as is frequently seen during an operation He did not think that intubation of the larynx would take the place of tracheotomy, it no doubt is of great benefit in those cases where the patient is likely to die unless some measure be quickly adopted which will give time enough to allow the operation of tracheotomy In the case under discussion the tube was worn sixty-eight hours continuously He had not seen a case of tracheotomy where the closure of the fenestra gave evidence that the trouble with the larynx or glottis was overcome in less than six days This was the shortest time in which he had been able to remove the tracheotomy tube

DR F E WAXHAM said that from his experience with intubation of the larynx he was thoroughly convinced of its utility, and its superiority over tracheotomy He had eight recoveries out of his first seventeen cases, a result which he claimed could not be approached by tracheotomy, especially in Chicago The ages of the patients varied from 11 months to 5 years, he considered these eight cases as being saved from certain death, as in only one case would tracheotomy have been permitted by the friends, and he had the corroborative evidence of other physicians as to the impending danger, and the urgent necessity of surgical interference Since his last report he had had a number of cases, and had performed the operation four times during the last week, one patient being only 11 months old, suffering from both laryngeal and pharyngeal diphtheria, the urgent symptoms were at once relieved In another case aged 18 months, where death was impending, the tube was introduced without difficulty and the child relieved, and recovery would without doubt have been the result had not the child died of pneumonia on the second day In another case, one of malignant diphtheria in a child of 2 years, the patient succumbed on the second day after the operation In another case he found the patient cold and livid, pulseless, and unconscious After the tube was introduced cold water was dashed on the child's face, and in about five minutes he looked around and asked for his father, took some milk and passed into a quiet sleep This child died from pneumonia three hours later Dr Waxham said that in the eight cases that recovered, in every instance false membrane was observed, when the tube was introduced the membrane was ejected, either in large flakes or broken down masses He recommended that in treatment after intubation nothing at all irritating should be given, as when a child takes fluid of any kind a few drops will trickle into the trachea and cause violent coughing, and this irritation will often lead to pneumonia In a child rugged and strong, bichromide of mercury may be given to hasten disintegration of false membrane The most remarkable case coming under his observation was a child of 4 years upon the verge of suffocation, when, upon the tube being introduced, a considerable portion of false membrane was thrown out through the tube and the violent symptoms subsided at once The thread was removed, and the second day after the operation the child was playing about the room and continued about the house during the four days that the tube was worn, and finally made an entire and perfect recovery Dr Waxham thought that in regard to the comparative value of tracheotomy and intubation very much might be said The text-books give as the percentage of recoveries from tracheotomy about one in three, but these statistics are made up from the most favorable reports If a physician has one recovery out of three or four cases he is justly proud of it and reports the case, on the other hand, if there is one recovery out of fifteen or twenty cases, no report is made He had known one physician to have operated fifty times with but two recoveries Dr Waxham thought that the thread should always be removed, as it is a constant cause of irritation, and that no difficulty need be experienced in removing the tube with extractors He thought intubation had a grand future

DR E FLETCHER INGALS did not take an enthusiastic view of intubation excepting for young children, when he thought it would be found more satisfactory than tracheotomy In very young children tracheotomy does not result well, and he thought intubation would be unsatisfactory in older ones until we have larger tubes He stated the accepted opinion of surgeons to be that a tube of less than one-fourth of an inch in diameter can not furnish sufficient air for a child to live on Dr Ingals thought that Dr Waxham had been remarkably successful with intubation, and had demonstrated its utility, for which he deserved credit Dr Ingals thought that intubation of the larynx is preferable to tracheotomy in children less than three and a half years of age, children much older than this cannot get a sufficient amount of air through the tube now in use He said, also, that in performing one operation he had had trouble with the gag, which was not large enough for the child, a boy of five years, who lifted his teeth from the gag and closed them on the doctor's finger He thought there was no need of the thread remaining, as there could be little difficulty in removing the tube Dr Ingals thought in cases where it is difficult to get the consent of friends, or where the conditions are such that tracheotomy cannot be performed right away, intubation would be of value, there are cases not membranous in which intubation may be of value The statistics looked pretty bad for tracheotomy but he had seen statistics of fifteen or sixteen cases where half of them were recoveries His success had not been quite so good, but he attributed this mainly to the fact that he had operated on five children who were almost dead, or at least had stopped breathing before the operation began He had the good fortune once to save a child who had not breathed for what seemed to him twenty minutes One of the strong points in favor of intubation is that it may be done early, and it does no harm even if unnecessary

DR H T BYFORD said there was another way of drawing the line which would more accurately describe the usefulness of the two operations Intubation seemed to him the operation for private practice, and statistics so far are comparatively favorable to it as such But the cooperation of the patient's friends, the preparation of the inspired air by passage through natural channels, the freedom of intubation from grave responsibility, its bloodlessness, the simplicity of treatment afterwards, as well as the greater rapidity with which the mucous membrane around the vocal chords will get well, are conditions which have less bearing in hospital practice, where we have trained nurses and all modern appliances, and there is more hope of success in tracheotomy While he did not think this latter operation favorable for private practice, such advantages as having the tube under the eye, and within reach of the fingers, of an attendant, the ease of local medication, the possibility of removing shreds of membrane and plugs of mucus, and of inspecting the parts by removing the tube, and the longer time the tube can be retained, these are things that do not pertain to intubation, and which, in hospital practice, must secure for it some consideration He said that there was one clinical fact that had not been mentioned in this connection, yet which, more than all other things put together, accounts for the success of intubation and the failure of tracheotomy as life-saving measures in the one the patient can cough, in the other he can not After intubation the patient can normally close the glottis, compress the inclosed air in the lungs, and with sudden explosive force expel everything that is sufficiently loosened This accounts for the fact that with such a small tube the patient experiences no difficulty After tracheotomy the patient has no means of compressing the air and expelling it with sudden explosive force, he can simply inspire and expire forcibly and after exhausting efforts get rid of a little of the mucus This desperate condition of affairs has led some surgeons to employ the dangerous and barbarous custom of introducing feathers or other irritants into the tube to stimulate the mucous membrane, which excites the patient and scatters the mucus both upwards and downwards When somebody invents an appliance which will enable the patient to really cough through the tube, then tracheotomy will be placed upon a rational basis, and will stand some chance of becoming a useful operation The doctor thought tracheotomy had made a poor showing for its years of trial

Dr G C Paoli said that malignant diphtheria is a morbid poison, and that in epidemic cases there are very few recoveries He stated that in such cases exudation does not take place in the larynx or pharynx, and that an operation would only result in sending the patient more quickly to another world

Dr W E Quine said that he had operated twelve times for tracheotomy and had not had one recovery in diphtheritic cases He knew he was not alone in an experience of unvarying failure in cases of this kind, and he knew some surgeons now regard tracheotomy with very little enthusiasm It seemed to Dr Quine unfair to place intubation of the larynx in contrast with tracheotomy upon the basis of the assumption that tracheotomy is always a *dernier ressort*, that it is done when the patient is absolutely moribund, and that intubation is done under the most favorable circumstances This is not the fact Dr Quine said he was personally cognizant of two of Dr Waxham's cases in which the patients were *in extremis*, and in which death would undoubtedly have occurred in two or three hours had not relief been afforded Surgeons rarely had occasion to perform tracheotomy under more discouraging circumstances

Dr J J M Angear said he wished to call attention to a physiological and anatomical fact that had not been alluded to, viz that the arytenoid cartilages are not mature and that the chink of the glottis is held open by positive muscular action in small children, whereas in adults and older persons the arytenoid cartilages are mature and the chink is never closed Dr Angear said that a large number of children who suffocate will suffocate when there is no membrane present to cause suffocation, but simply some diseased condition that has interfered with the action of the delicate little muscles that draw back the arytenoid cartilages When inflammatory action has interfered with these muscles drawing back the arytenoid cartilages, some mechanical interference like this tube will assist these muscles to keep the chink of the glottis open and let air in He thought a large number of children who died of diphtheria did not choke to death, but died of poison in the system, and he did not think either the tube or tracheotomy, or any other process, could save them If there was interference with the opening of the chink of the glottis he had no doubt the introduction of the tube would save the life of the child

Dr J S Knox said that the curses of tracheotomy are the subsequent thoracic complications, either heart-clogs or congestion and inflammation of the lungs, producing fatal results, and the reason probably is that tracheotomy is the final resort in cases of laryngeal obstruction He thought that if tracheotomy were performed as early as intubation, there would be fifty per cent of recoveries The great advantage of intubation is that it can be performed early, and the early operation of intubation would no doubt save many a life that tracheotomy would not save performed late He thought that tracheotomy performed as early as intubation would show as good results

The President said that he did not intend to say anything against the practice of intubation, but he did not believe that it would take the place of tracheotomy Intubation has had but a very short trial, and it is not yet time to pronounce it better than tracheotomy The early experience of the President in tracheotomy had been almost the same as that of Dr Waxham in intubation In the first fifteen cases operated on but half of them recovered, and his later experience was better than that reported by Dr Waxham, as within the last month he had had three cases of tracheotomy, all recoveries, while Dr Waxham reports four cases of intubation, all fatal So far as his own personal experience went, he thought tracheotomy had the advantage The President thought that if he should put a tube in a child's throat for the relief of laryngitis and the child died without his having performed tracheotomy, he should consider himself very much to blame He had no doubt that cases of extreme diphtheritic laryngitis got well after tracheotomy, he had seen diphtheria of the pharynx and of the larynx recover after tracheotomy Although he did not feel enthusiastic about intubation he thought it had a very good place and in many cases might be very useful, but could never supplant tracheotomy

Dr Waxham said he had never found the tube occluded when it was removed In one case when he introduced the tube a portion of the membrane was crowded down ahead of it, obstructing it entirely, and the tube was ejected and was then completely filled with membrane, the child recovered subsequently On removing the tube on the fourth or fifth day he did not find it occluded

Dr A B Strong said, in conclusion, that he had had some experience with tracheotomy, having had twelve cases with but one recovery He had no doubt that in cases of diphtheria the membrane could come up through the opening The case read was reported as spasmodic croup, and was not supposed to be one of false membrane, but he believed the child would have died without interference, and that belief was shared by Dr Danforth, the attending physician Dr Strong said that he would hardly feel safe in leaving the tube in the trachea of a child without the thread He agreed with the President that large pieces of membrane could not readily pass through such a long tube In the case reported the tube was entirely free from membrane or pus when taken out

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, January 13, 1886

THE PRESIDENT, C H A KLEINSCHMIDT, M D, IN THE CHAIR

T E McARDLE, M D, SECRETARY

(Concluded from page 160)

DR H D FRY read a paper entitled

SOME REMARKS ON THE MANAGEMENT OF PROTRACTED FIRST STAGE OF LABOR

(See page 171)

DR J TABER JOHNSON congratulated Dr Fry in having brought this subject to the attention of the Society He believed that a great deal of danger from a protracted first stage is due to its deleterious influence on the second stage The patient enters upon this latter stage with diminished strength The whole household, in fact, is demoralized The mother and child are in danger, the latter from asphyxiation, the former from long continued pressure Dr Fry had not referred to some of the prominent causes of the trouble under consideration, such as malpresentations, ossification of the fontanelles, failure of the head to properly mold itself, unusual small size of pelvis, rigidity of the os, and so on Physicians have been governed too much by the oft repeated axiom concerning meddlesome midwifery Proper scientific interference is always permissible when intelligently applied Dr Johnson had used electricity in labor cases, and whil he is not such an enthusiast as Dr Baird, yet he had derived benefit from it, and had great hopes of its future The faradic current seems to steady the contractions, in a word, to render intermittent pains rhythmical Chloral had also proved an effective agent in Dr Johnson's hands He gives fifteen grains every hour until the agonizing intermittent pains are quieted and the patient is enabled to bear down with better results The warm douche against the cervix is often beneficial A large part of the gynecologist's practice is due to unattended labor cases It will not do for the accoucheur to be a mere midwife, he must know when interference is demanded by the exigencies of the case In reply to a question by Dr Fry, Dr Johnson said that when he had used electricity he had not found the pains less painful, but stronger and more effective

DR A Y P GARNETT was sorry that Dr Taber Johnson had not given us some more enlightened views on the points under discussion He apparently in the same breath urges stimulation and relaxation. He employs faradization to shorten the first stage because it produces uterine contractions, and he counsels the use of chloral for the same purpose because of its relaxing effect Dr Garnett had no experience with electricity in labor, but he was desirous of knowing whether a current strong enough to produce uterine contractions might not have a harmful effect upon the fœtus These gentlemen adopt means which have for their effects the same results obtained formerly by opium and bleeding He was not a strong advocate of early interference, but believed in applying forceps when occasion required

DR JOHNSON did not pretend to any special knowledge of electricity In labor cases this means must be employed delicately and properly The least injurious way is to apply one pole to the sacral region and the other to the fundus uteri, or the accoucheur may hold one electrode in his hand and pass the other hand gently over the woman's abdomen It is true the faradic current is used in extrauterine pregnancy for the purpose of killing the fœtus

DR GARNETT asked Dr Johnson the exact physiological action of ergot on the muscular fibres of the uterus Ergot contracts and electricity contracts, yet Dr Johnson advocates the use of one and deprecates the employment of the other

DR JOHNSON replied that ergot produced tonic contractions of the unstriped muscular fibres of the uterus, oftentimes shutting off the natural blood supply to the child Electricity can be applied at will and need not be used so as to cause continuous contractions Ergot also contracts the short circular fibres of the os In reply to a question by Dr Fry, Dr Johnson said he had used a Kidder's battery with the ordinary hand electrodes He placed one sponge at the back of the patient and held the other with his hand over the abdomen

DR FRY said he had mentioned in his paper the deleterious effect upon the first stage of the failure of the uterus and its contents to descend within the pelvic canal The causes of delay which Dr Johnson claims that he had overlooked were just such that prevented this descent He thought Dr Garnett took a narrow minded view of the subject In one case sedatives may be required and in another stimulants would be proper The rational method of treating these cases is to find out the influence at work which prevents dilatation of the os, and to employ that remedy indicated for its relief Dr Fry exhibited the electrodes used by Dr Baird He believed that electricity would prove a powerful and valuable aid in overcoming feeble uterine contractions His experience with it held out such a promise, but he did not find that the current gave relief to pain

DR J M TONER thought there was some misapprehension as to the neglect of physicians in the treatment of protracted labor cases and their indifference to the sufferings of parturient women There clinical fact that had not been mentioned in this connection, yet which, more than all other things put together, accounts for the success of intubation and the failure of tracheotomy as life-saving measures; in the one the patient can cough, in the other he can not. After intubation the patient can normally close the glottis, compress the inclosed air in the lungs, and with sudden explosive force expel everything that is sufficiently loosened. This accounts for the fact that with such a small tube the patient experiences no difficulty. After tracheotomy the patient has no means of compressing the air and expelling it with sudden explosive force, he can simply inspire and expire forcibly and after exhausting efforts get rid of a little of the mucus. This desperate condition of affairs has led some surgeons to employ the dangerous and barbarous custom of introducing feathers or other irritants into the tube to stimulate the mucous membrane, which excites the patient and scatters the mucus both upwards and downwards. When somebody invents an appliance which will enable the patient to really cough through the tube, then tracheotomy will be placed upon a rational basis, and will stand some chance of becoming a useful operation. The doctor thought tracheotomy had made a poor showing for its years of trial.

Dr. G. C. Paoli said that malignant diphtheria is a morbid poison, and that in epidemic cases there are very few recoveries. He stated that in such cases exudation does not take place in the larynx or pharynx, and that an operation would only result in sending the patient more quickly to another world.

Dr. W. E. Quine said that he had operated twelve times for tracheotomy and had not had one recovery in diphtheritic cases. He knew he was not alone in an experience of unvarying failure in cases of this kind, and he knew some surgeons now regard tracheotomy with very little enthusiasm. It seemed to Dr. Quine unfair to place intubation of the larynx in contrast with tracheotomy upon the basis of the assumption that tracheotomy is always a *dernier ressort*, that it is done when the patient is absolutely moribund, and that intubation is done under the most favorable circumstances. This is not the fact. Dr. Quine said he was personally cognizant of two of Dr. Waxham's cases in which the patients were *in extremis*, and in which death would undoubtedly have occurred in two or three hours had not relief been afforded. Surgeons rarely had occasion to perform tracheotomy under more discouraging circumstances.

Dr. J. J. M. Angear said he wished to call attention to a physiological and anatomical fact that had not been alluded to, viz.: that the arytenoid cartilages are not mature and that the chink of the glottis is held open by positive muscular action in small children, whereas in adults and older persons the arytenoid cartilages are mature and the chink is never closed. Dr. Angear said that a large number of children who suffocate will suffocate when there is no membrane present to cause suffocation, but simply some diseased condition that has interfered with the action of the delicate little muscles that draw back the arytenoid cartilages. When inflammatory action has interfered with these muscles drawing back the arytenoid cartilages, some mechanical interference like this tube will assist these muscles to keep the chink of the glottis open and let air in. He thought a large number of children who died of diphtheria did not choke to death, but died of poison in the system, and he did not think either the tube or tracheotomy, or any other process, could save them. If there was interference with the opening of the chink of the glottis he had no doubt the introduction of the tube would save the life of the child.

Dr. J. S. Knox said that the curses of tracheotomy are the subsequent thoracic complications, either heart-clogs or congestion and inflammation of the lungs, producing fatal results, and the reason probably is that tracheotomy is the final resort in cases of laryngeal obstruction. He thought that if tracheotomy were performed as early as intubation, there would be fifty per cent. of recoveries. The great advantage of intubation is that it can be performed early, and the early operation of intubation would no doubt save many a life that tracheotomy would not save performed late. He thought that tracheotomy performed as early as intubation would show as good results.

The President said that he did not intend to say anything against the practice of intubation, but he did not believe that it would take the place of tracheotomy. Intubation has had but a very short trial, and it is not yet time to pronounce it better than tracheotomy. The early experience of the President in tracheotomy had been almost the same as that of Dr. Waxham in intubation. In the first fifteen cases operated on but half of them recovered, and his later experience was better than that reported by Dr. Waxham, as within the last month he had had three cases of tracheotomy, all recoveries, while Dr. Waxham reports four cases of intubation, all fatal. So far as his own personal experience went, he thought tracheotomy had the advantage. The President thought that if he should put a tube in a child's throat for the relief of laryngitis and the child died without his having performed tracheotomy, he should consider himself very much to blame. He had no doubt that cases of extreme diphtheritic laryngitis got well after tracheotomy, he had seen diphtheria of the pharynx and of the larynx recover after tracheotomy. Although he did not feel enthusiastic about intubation he thought it had a very good place and in many cases might be very useful, but could never supplant tracheotomy.

Dr. Waxham said he had never found the tube occluded when it was removed. In one case when he introduced the tube a portion of the membrane was crowded down ahead of it, obstructing it entirely, and the tube was ejected and was then completely filled with membrane, the child recovered subsequently. On removing the tube on the fourth or fifth day he did not find it occluded.

Dr. A. B. Strong said, in conclusion, that he had had some experience with tracheotomy, having had twelve cases with but one recovery. He had no doubt that in cases of diphtheria the membrane could come up through the opening The case read was reported as spasmodic croup, and was not supposed to be one of false membrane, but he believed the child would have died without interference, and that belief was shared by Dr Danforth, the attending physician Dr Strong said that he would hardly feel safe in leaving the tube in the trachea of a child without the thread He agreed with the President that large pieces of membrane could not readily pass through such a long tube In the case reported the tube was entirely free from membrane or pus when taken out

Dr H D Fry read a paper entitled

SOME REMARKS ON THE MANAGEMENT OF PROTRACTED FIRST STAGE OF LABOR

(See page 171)

Dr J Taber Johnson congratulated Dr Fry in having brought this subject to the attention of the Society He believed that a great deal of danger from a protracted first stage is due to its deleterious influence on the second stage The patient enters upon this latter stage with diminished strength The whole household, in fact, is demoralized The mother and child are in danger, the latter from asphyxiation, the former from long-continued pressure Dr Fry had not referred to some of the prominent causes of the trouble under consideration, such as malpresentations, ossification of the fontanelles, failure of the head to properly mold itself, unusual small size of pelvis, rigidity of the os, and so on Physicians have been governed too much by the oft repeated axiom concerning meddlesome midwifery Proper scientific interference is always permissible when intelligently applied Dr Johnson had used electricity in labor cases, and whil he is not such an enthusiast as Dr Baird, yet he had derived benefit from it, and had great hopes of its future The faradic current seems to steady the contractions, in a word, to render intermittent pains rhythmical Chloral had also proved an effective agent in Dr Johnson's hands He gives fifteen grains every hour until the agonizing intermittent pains are quieted and the patient is enabled to bear down with better results The warm douche against the cervix is often beneficial A large part of the gynecologist's practice is due to unattended labor cases It will not do for the accoucheur to be a mere midwife, he must know when interference is demanded by the exigencies of the case In reply to a question by Dr Fry, Dr Johnson said that when he had used electricity he had not found the pains less painful, but stronger and more effective

Dr A Y P Garnett was sorry that Dr Taber Johnson had not given us some more enlightened views on the points under discussion He apparently in the same breath urges stimulation and relaxation He employs faradization to shorten the first stage because it produces uterine contractions, and he counsels the use of chloral for the same purpose because of its relaxing effect Dr Garnett had no experience with electricity in labor, but he was desirous of knowing whether a current strong enough to produce uterine contractions might not have a harmful effect upon the fœtus These gentlemen adopt means which have for their effects the same results obtained formerly by opium and bleeding He was not a strong advocate of early interference, but believed in applying forceps when occasion required

Dr Johnson did not pretend to any special knowledge of electricity In labor cases this means must be employed delicately and properly The least injurious way is to apply one pole to the sacral region and the other to the fundus uteri, or the accoucheur may hold one electrode in his hand and pass the other hand gently over the woman's abdomen It is true the faradic current is used in extra-uterine pregnancy for the purpose of killing the fœtus

Dr Garnett asked Dr Johnson the exact physiological action of ergot on the muscular fibres of the uterus Ergot contracts and electricity contracts, yet Dr Johnson advocates the use of one and deprecates the employment of the other

Dr Johnson replied that ergot produced tonic contractions of the unstriped muscular fibres of the uterus, oftentimes shutting off the natural blood supply to the child Electricity can be applied at will and need not be used so as to cause continuous contractions Ergot also contracts the short circular fibres of the os In reply to a question by Dr Fry, Dr Johnson said he had used a Kidder's battery with the ordinary hand electrodes He placed one sponge at the back of the patient and held the other with his hand over the abdomen

Dr Fry said he had mentioned in his paper the deleterious effect upon the first stage of the failure of the uterus and its contents to descend within the pelvic canal The causes of delay which Dr Johnson claims that he had overlooked were just such that prevented this descent He thought Dr Garnett took a narrow-minded view of the subject In one case sedatives may be required and in another stimulants would be proper The rational method of treating these cases is to find out the influence at work which prevents dilatation of the os, and to employ that remedy indicated for its relief Dr Fry exhibited the electrodes used by Dr Baird He believed that electricity would prove a powerful and valuable aid in overcoming feeble uterine contractions His experience with it held out such a promise, but he did not find that the current gave relief to pain

Dr J M Toner thought there was some misapprehension as to the neglect of physicians in the treatment of protracted labor cases and their indifference to the sufferings of parturient women There may be some difficulty at first in determining which are true and which are false labor pains. The beginning of labor is not always easily determined. He advocated the use of hot water and unguents in treating a sensitive and dry vagina.

DR. FRY said he had reference to those pains which were strong enough to keep the patient awake, prevent her from obtaining proper nourishment, which produce nervous exhaustion, and yet do not assist the progress of labor. The moisture obtained from the natural secretions is better than all ointments. Dr. Fry spoke of the benefits to be derived from the proper use of morphia and chloral, and called attention to the method of lifting the head until the bag of waters is formed.

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

Scarlet Fever from Milk—The Society of Public Analysts—St. Bartholomew's Hospital—Pasteur's Rule concerning Rabies—Spontaneous Hydrophobia.

Dr. Wynter Blyth, Medical Officer of Health to the Marylebone Vestry, has just presented to that body a report which throws new and unexpected light on the origin of a recent outbreak of scarlet fever. A minute examination leads to the inference that every case in the outbreak referred to was traceable to the drinking of milk from a cow or cows on a model farm some distance from town. Dr. Blyth, after mentioning that Dr. Power has been deputed to investigate the matter, says, one of the cows has been bought and removed to the Brown Institution, where Dr. Klein is making experiments with the milk and secretions. It appears that between December 1st and 29th there were in the parish sixty cases of illness having this one thing in common, that the patients drank milk from one of the three dairies getting their supply from the same model farm. Some of the sufferers had simple sore throat, others a mild attack of scarlet fever, a few a severe attack. In one case death resulted. Those who drank no milk save that which had been boiled, were not attacked, and most of those who merely took a little milk in tea and coffee escaped. Children taking considerable quantities of lukewarm or unboiled milk, and adults drinking raw milk formed the bulk of cases. Several cases of infection from the cream occurred, and I had reason to believe that the disease-influence was in a more concentrated form in the cream than in the milk. This report is necessarily incomplete, for the full history will not be known until Dr. Power publishes his report and gives details relative to cases in the parishes of Hampstead and Hendon, infected either direct from the farm or indirectly through dairy, together with the results of the examination of the cows and Dr. Klein's experiments. There can be no doubt but that from these data most important discoveries may be made as to the origin of scarlet fever, and the results are awaited with much interest by the profession.

At the annual meeting of the Society of Public Analysts, Dr. Alfred Hill, of Birmingham, was re-elected President for the ensuing year. The President in the course of his address referred to the work done by the Society during the year in the advancement of science and in the improvement of analytical methods, and alluded to several matters of interest in connection with the working of the "Sale of Food and Drugs Act."

The annual Christmas festivities have just been held in the Grand Hall of St. Bartholomew's Hospital. A singular interest attaches to the history of this well known hospital, from the fact that more than 700 years ago it was founded by one Rahere, who had been the king's jester, but later in life became a monk, whereupon he made a pilgrimage to Rome. There he visited the monastery of St. Bartholomew, situated upon an island in the centre of the Holy City, where the sick were taken in and tended by the monks. On returning to England he obtained an interview with the king, who granted him the space of ground outside of the then limits of the city—the same site on which the present hospital stands—then, as now, known by the name of Smithfield. From that date the hospital has been doing the good work in which it is now engaged, having been enriched from time by charters and grants of lands from successive monarchs, and legacies from the pious and charitable. It now possesses 13,000 acres of landed property in the home counties, and 2000 houses in the city and other parts of the metropolis. These estates are administered by a treasurer and a board of management. The nursing staff is nearly 200 strong, and consists of sisters who are distinguished by their blue dresses, the nurses being attired in dark gray and the probationers in light gray. These probationers are divided into two classes. Forty are ordinary probationers, well educated women, who bind themselves for three years, some of them daughters of clergymen, and who receive payment for their services, whilst about eighteen are special probationers, who pay a guinea a week for instruction in the science of nursing, and for whom a home, presided over by a lady superintendent, is provided. To the present treasurer is to be ascribed the credit of introducing the system of training nurses at St. Bartholomew's, for until his appointment as treasurer, in 1873, there was not a single skilled nurse in the establishment, although there were many in the newest of our metropolitan hospitals—St. Thomas's. It should be mentioned that with the steadily increasing value of the hospital's house property—for the landed estates are, owing to the general agricultural depression, not in a very flourishing condition—is a parallel increase of expenditure, consequent on the entire reform in the system of nursing, the rebuilding of schools, museums and class rooms, and the maintenance of a convalescent home at Swanley, in Kent, into which home are admitted patients only who have passed through the hospital. The programme of the entertainment consisted of two dramatic pieces, sustained with much ability by the members of the Hospital Dramatic Club. Between the pieces was a concert, the part songs in which were admirably rendered by members of the Hospital nursing staff and of the Hospital Musical Society The whole was thoroughly enjoyed by a large audience

M Pasteur has laid down the following rules as to hydrophobia in dogs, which will be read with interest "Every dog, whether it eats or not, that is attacked with rabies, dies in a few days When it eats, death is delayed a few days, but that is all It cannot live for more than ten days, and will probably die on the eighth During the interval rabid symptoms will be shown Lock up, therefore, and chain the dog Be careful in feeding it, and in cleaning away its litter not to go within biting distance If it survives the tenth day you may have an easy mind If it has bitten a person before being secured, the wound must be attended to It should on no account be neglected The spittle of a perfectly healthy dog may contain microbes which would cause an abscess In very rare cases the bites of such dogs have caused septic blood poisoning If rabid symptoms declare themselves, a person who has been bitten should at once go to M Pasteur's laboratory, and he will be happy to treat them for rabies Two Hungarian soldiers who were lately bitten by a mad dog have been sent to Paris at the expense of the Government to be attended by M Pasteur A case has just been mentioned of well-established "spontaneous hydrophobia" in a man aged 29 Not only did all the symptoms which characterize that malady declare themselves, but the matter taken from the patient's body when he died communicated it to rabbits inoculated therewith G O M

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

Prof Peter on the Parasitic Doctrines of Disease

I have more than once referred to Dr Peter, Professor of Medical Pathology at the Paris School of Medicine, as being an avowed adversary of the parasitic doctrine that is gaining ground in the science and art of medicine of the present day As the parasitic doctrines have been published in the medical journals almost without comment, it has been inferred in many quarters that these doctrines are unassailable It may, therefore, be interesting to know what arguments the adversaries of these doctrines have to advance against them, and it is with this view that I here reproduce notes of a lecture recently delivered by Professor Peter on the subject The necessary distinction, said the Professor, between the lesion and the malady has been ignored by the physicians who look upon tuberculosis as a parasitic malady and consider the rod, which the microscope has revealed in certain tuberculous lesions, as the cause of the malady Thus we have now two tuberculoses The tuberculosis of the old school was a general, spontaneous, intrinsic malady, created by the organism under the influence of innutrition and other debilitating causes

The tuberculosis of the new school is a malady of extrinsic or accidental origin, produced by the invasion of a foreign body According to this view of the matter, the bacillus is at the same time the cause and the criterion of the nature of the malady It consequently follows that if, in the lesions which clinicians have always looked upon as being scrofulous, bacilli are found, these lesions ought henceforth to be reputed tuberculous, this would lead to the admission of the identity of scrofula and tuberculosis, which would evince gross misapprehension of clinical observation If, on the other hand, in granulations manifestly tuberculous, one does not find bacilli, but zooglœa, the partisans of the parasitic doctrine conclude that the malady is tuberculous, but of a zooglœic tuberculosis, which would be the height of confusion After giving a description of the bacilli and the various maladies in which they are found, Professor Peter admits that the discovery of Koch has been a real conquest Koch has taught us, that in revealing the existence of bacilli, to better recognize the tubercle, as Laennec taught us to recognize the divers modalities of the tubercle, the grey granulation The crude, caseous tubercle, grey infiltration So far the discovery of the bacillus of Koch is a conquest for morbid anatomy, it is also a conquest for semiology, as the presence of the bacillus permits us to distinguish the sputum of a tuberculous patient from that of an ordinary bronchitic case

But since the discovery of Koch, the profession seems to have gone too far in the wake of enthusiasm It was believed that the recognition of this rod, a pretended parasite, was going to open a new era to the therapeutics of tuberculosis It is a strange error which consists in deducing therapeutics from morbid anatomy, which is only the natural history of lesions, as semiology is the natural history of symptoms, and in confounding the lesion, which is only a product, with the malady, which is an act, it will be just as if one confounded surgery with medicine The lesion is a "*fait accompli*" It is a manifestation of a deviation of nature, but at the same time acting The surgeon acts on the lesion when he treats a fracture, the physician struggles against an act when he treats a case of pneumonia or of pleurisy It is to the living nature of the pneumonic, to the vitality of the pleuritic, that he should address himself Medically speaking, in discovering the bacillus, there was no therapeutic conquest made, as the parasite was considered, hypothetically, the cause of tuberculosis, it was thought that by impeding the life of the parasite one would cure the tuberculous affection This, said the Professor, is a gross error

After giving a description of the origin and development of the various bacilli, as shown in the laboratory, M Peter thinks that these pretended parasites originate in our own organisms, that the different viruses generated in us may be transformed under certain influences into agents of protection of the organism, and M Pasteur ought to be commended for his researches and his experiments, but we must not cry victory too soon

In concluding his lecture, Professor Peter explained why he should be so embittered against the parasitic doctrines, "which seem to spread after the fashion of the parasites," it is because those in favor of the doctrine "are mistaken in taking the effect for the cause, a morbid product for a generator of disease, and analogy for identity." Certain consequences of such confusion broke out in the famous inoculations of Ferrán, who pretended to produce an experimental cholera, as are so many experiments of the kind as performed in laboratories. As there is no error which has not its sanction, the parasitic doctrine has had one in a social and medical point of view. To consider tuberculosis as parasitic is to admit that all phthisical subjects had caught the disease by contagion and that they can communicate it to others by contagion. The therapeutic consequence is to seek to combat the parasite without, in organizing quarantines against tuberculous subjects, and within in administering microbicide substances such as creosote, carbolic acid, etc. Finally, M. Peter finds the social sanction in the reproduction, in our times, of savage scenes worthy of another age. That which was seen lately at Naples and at Sicily, for the cholera, takes place every day, every year, in certain towns in the south of Italy, where the landlords compel the unfortunate subjects of phthisis to cancel their leases. It is to prevent the generalization of such monstrous acts that M. Peter believes it his duty to combat with all his force, to convince his confrères, to instil his ideas into his pupils, and to keep the public on their guard against the delusions which trouble the brains of our contemporaries.

Prof. Peter was a pupil and friend of Trousseau, whose doctrines he is supposed to have fully imbibed and from his present position his opinions are worthy of some consideration.

A. B.

DOMESTIC CORRESPONDENCE

THE NINTH INTERNATIONAL MEDICAL CONGRESS

To the Editor of the Journal.

Dear Sir:—There is one significant fact in this matter of the next meeting of the International Medical Congress, which has not attracted attention, which to the writer seems important, namely, the *undue haste* exhibited by the Original Committee of Seven to get out their work *ad captandum vulgus*. The editor of the *Philadelphia Medical News*, in his specious editorial reply to "Country Doctor" in his issue of January 30, although *he was one of the seven*, carefully abstains from any explanation of it.

These seven, whom he with characteristic modesty describes as "*the most eminent contributors to the advancement of medical science* in the country in which the Congress was to meet," were commissioned by the American Medical Association in May, 1884, to go to Copenhagen and invite the Congress to hold its next meeting in this country. They satisfactorily performed this office, and through their spokesman promised the members a generous welcome, he pledging himself to do a variety of things without reservation (expressed at least), as to the contingency of his not being allowed to have everything his own way (I do not mean the editor of the *Medical News*). They hied home, went to work upon an organization which showed the evidences of the personal preferences and enmities of some of the individual seven, and published all over Europe their cut and dried scheme for a meeting which was not to take place until 1887, without waiting the few weeks before the meeting of the American Medical Association, to report their work to that Association in whose name, by whose authority and under whose appointment only they had anything whatever to do with the matter.

Now let us see how differently things were managed for the Seventh Session of the International Medical Congress, which was held in London in 1881. At the Sixth Session of the Congress, held at Amsterdam in September, 1879, it was determined to hold the next meeting at London, in 1881 and in September, 1880, one year after the adjournment of this Sixth Session, and *only eleven months* before the convening of the Seventh, a circular was issued from London, signed J. Risdon Bennett, Chairman of the Executive Committee, and William MacCormac, Secretary-General, which stated as follows:

> "We have the honor to inform you that at the close of the Sixth Session of the International Medical Congress, held last September in Amsterdam, under the presidency of Professor Donders, of Utrecht, a unanimous desire was expressed that the next meeting should take place in Great Britain in 1881.
>
> "This desire having been communicated to the presidents of the Royal College of Physicians and Surgeons in London, they convened a meeting of delegates from the various universities, colleges and other public bodies of the United Kingdom, including the principal medical societies, the British Medical Association, and the medical departments of the army, navy and India office, in order to obtain a thoroughly national representation of feeling and opinion.
>
> "The response to this appeal having been most cordial, it was decided at the meeting of delegates thus convened to comply with the wish expressed at the meeting at Amsterdam, and to hold the Congress in London. A general committee of organization was appointed, an executive committe, and a reception committee to carry out the necessary details.
>
> * * * * * * *
>
> "The work of the Congress will be carried on in fifteen Sections. The days of the meeting will extend from Wednesday, the 3d, to Tuesday, the 9th of August, both days included. A reception of welcome will take place on the evening of August 2."

The London *Medical Times and Gazette* (since gone out of existence) rebuked the *London Lancet* for according to the American Medical Association any consideration whatever in the organization and control of the Congress, asserting that it only has a membership of 3,000 members against 40,000 physicians excluded from the Congress by its present Committee on Organization. The *British Medical Journal*, which is no better informed than this as to the representative character of the American Medical Association, may well be suspected of arguing *ex parte*, but there are American medical journals which have reproduced this unfounded statement without contradiction or correction. Assuming that the American Medical Association was not the only source whence "to obtain a thoroughly national representation of feeling and opinion," as was obtained in Great Britain, on what assumption can the Original Committee of Seven or the coadjutors they themselves selected to constitute the General Committee with them, claim to have accomplished this result?

Were they authorized to act for the American Surgical Association, the American Gynecological Association, the American Ophthalmological and Otological Association, the American Laryngological Association, the American Academy of Medicine, the American Climatological Association, the American Public Health Association, the Medical Departments of the Army, Navy and Marine Hospital Service, the Canadian Medical Association, or, indeed for anything but the medical profession as represented by the American Medical Association?

If there is any doubt in Europe that a *thoroughly national* representation of the profession of medicine in this country can be obtained through the American Medical Association, then let there be "convened a meeting of delegates from the various universities, colleges and other public bodies" in the United States (and Canada), including the principal medical societies, the American Medical Association and the Medical Departments of the Army, Navy and Marine Hospital Service, in order to obtain such a thoroughly national representation as was done at London There is ample time for such a meeting The Ninth Session of the Congress need not assemble until the autumn of 1887 There is not such a mighty need of preparation that an active Executive Committee cannot accomplish it all within six months Many of the previous meetings of the International Medical Congress have been held at intervals of only two years, thus

The First Session was held at Paris, in 1867, the Second in Florence, in 1869, the Third in Vienna, in 1873 the Fourth in Brussels, in 1875, the Fifth in Geneva, in 1877, the Sixth in Amsterdam, in 1879, the Seventh in London, in 1881, the Eighth in Copenhagen, in 1884, and the Ninth will be held in Washton, in 1887

If the American Medical Association cannot be entrusted with the task of organizing the Congress, *in the* name of the whole medical profession of this country, through its present Executive Committee, certainly the Original Committee of Seven, also appointed by it, can allege still less sanction for their dictatorial proceedings When the editor of the *Medical News*, who was also one of the Seven, "one of the most eminent contributors to the advancement of medical science" in his country, Member of the General Committee and Chairman of the Executive Committee, writes to "Country Doctor" that "at both the London and Copenhagen meetings *irregular* physicians are known to have inscribed their names on the register and the fact *did not in the least* disturb the Committee on Organization or detract from the success of the meeting," does he intend the medical profession to understand that subscription to the Code of Ethics of the American Medical Association does not mean, so far as he and the rest of the Original Committee of Seven are concerned, an honest, manly belief in its principles, acceptance of its restrictions and observation of its obligations, at all times and under all circumstances, but that he and they did similarly intend not to be in the least disturbed when *irregular* physicians inscribed their names on the register, and to sit in cheek-by jowl fraternity with them in a way no New York *New Coder* ever dreamed of doing? In this country, be it remembered, the homœopath is not the only species of the *irregular* physicians, but the eclectic and electric—the botanic and the hygeio-therapeutic—and a dozen more, are just as *legally* recognized as the editor of the *Philadelphia Medical News* MEDICUS

BOOK REVIEWS

PROCEEDINGS OF THE NEBRASKA STATE MEDICAL SOCIETY Seventeenth Annual Session, held at Grand Island, May 26–28, 1885 8vo, pp 385 Lincoln 1885

This well-printed volume of Transactions contains much more interesting and valuable material than is usually found in State Society Transactions, and the papers are conveniently classified under their proper sections of medicine, surgery, etc Under the Section on Surgery we find seven papers, all of some and some of great interest

The first surgical paper is the history of a case of *Penetrating Gunshot Wound of the Abdomen*, by Dr J K I Duncan, of DeWitt The patient recovered under treatment by opium and rest, though the ball penetrated the intestine, as shown by the fact that it was passed with the fæces The author assumes in the paper that the bullet, 38 calibre, injured the left kidney, the assumption being based on the fact that a few blood corpuscles were found in the urine on the fourth day As the ball entered the abdomen about one inch above the umbilicus, and then lodged in the intestine it does not seem possible that it could have reached the kidney, even though it "ranged inward, downward, and somewhat to the left"

Dr Duncan also reports a case of *Compound Fracture of the Skull, with Depression*, in which the skull was trephined, and recovery resulted The case was that of a boy, age not given, over whose head one wheel of a wagon loaded with grain had passed He was picked up in an unconscious condition, in which he was when Dr Duncan saw him about twenty eight hours after the injury Examination showed a fracture of the right parietal bone over the middle posterior portion, and extending into the posterior superior portion of the squamous portion of the temporal bone Having obtained assistance Dr Duncan made a semi circular incision extending somewhat over the sound portion of the parietal, and found a depressed fracture The centre pin of a trephine was placed on the sound table of the parietal bone, superior to the upper line of fracture, so near the fracture that a portion of the circle of the groove (using Galt's conical trephine) would extend partly over the depressed portion of the bone and internal to the line of fracture, making the groove evenly to the internal table, thus enabling him to remove the disk very readily One portion of the depressed bone had penetrated the dura mater, and was removed entire, the other portion was elevated The whole wound was then dressed antiseptically The wound was dressed on the third day, and the stitches were removed and a collodion and cotton dressing put on the sixth day. A fortnight later the boy was in perfect health. In connection with this case we may mention one of *Depressed Fracture of the Skull, with Laceration of the Dura Mater and Loss of Brain Tissue,* reported by Dr. M. L. Hildreth, of Lyons. A boy, aet. 6 years, was kicked on the top of the head by a horse. There was a contused wound of the scalp extending backwards and to the right from a point one-half an inch to the right of the median line, and at about the junction of the frontal and parietal bones, for a distance of about five inches. Anteriorly the wound extended through the bone, and one edge of the fracture was depressed to the extent of about half an inch. There was some twitching of the extremities, but no paralysis, and the patient was "indifferent on being aroused, and inclined to be let alone." Having failed to elevate the depressed bone with such instruments as he had with him, Dr. Hildreth determined not to trephine unless subsequent symptoms should demand it, the idea being that the loss of brain tissue would obviate the tendency to compression. He was inclined to think that it would be better to leave the depressed portion of bone where it was than to create a cavity by elevating it, and thus render drainage less perfect. The scalp was shaved, drainage provided for, adhesive plaster to retain flaps, antiseptic compresses, and bandage. A considerable amount of sloughing occurred under one flap, which was badly contused. Brain tissue continued to escape from the opening for about ten days, aggregating the amount of f℥ss, when it ceased and the opening filled with fibrous tissue. Two small pieces of detached bone came away during the process of healing. Recovery took place without unfavorable symptoms. (The case was reported five months after the occurrence of the accident.)

The dictum of Legouest, "whenever there is a doubt whether trephining should be done, this doubt is probably an indication that the operation should be performed," ought to be paraphrased "whenever there is a doubt as to whether a depressed portion of bone should be elevated, this doubt is an indication that it should be elevated." In the case reported by Dr. Hildreth it is very doubtful if so much as half an ounce of brain tissue would have escaped had the depressed portion of bone been elevated. In any case of doubt it is certainly better to incur the comparatively slight risks of early operation than the greater risks of a probably late operation, or subsequent epilepsy or insanity. In the case under consideration it seems that whatever drainage was required could certainly be better established even after the creation of a cavity than by running the risk of a cavity of suppuration under the depression where it could not be easily reached. There can scarcely be a doubt that it is better to operate when the depression is marked, even without brain symptoms, and a depression of three eighths or one half of an inch is to be regarded as marked depression. Dr. Hildreth also reports an interesting case of *Severe Concussion of the Spine, with probable Hæmorrhage,* due to a fall upon the back on frozen ground, from a height of fifty feet. There was complete motor paralysis below the 9th dorsal vertebra, with hyperæsthesia of legs and feet, and subsequent myelomeningitis. Belladonna, bromide of potassium, and ergot, with blisters on either side of the spine opposite the point of injury, were administered during the period of fever. The patient was able to walk with a cane in the course of six weeks, and continued to improve, but the paralysis of the bladder and rectum continued. Dr. J. S. Leonhardt, of Seward, reports three cases of fracture, two of the superior maxilla, and one of the surgical neck of the humerus, which were successfully and ingeniously treated. In the Section on Forensic Medicine and Toxicology is another interesting paper by Dr. Leonhardt, on *Six Cases of Poisoning with Treatment,* the poisoning agents being Blackberry Balsam, phosphorus, aconite, carbolic acid, arsenious acid, and three cases of poisoning by nutmeg, all of which recovered.

On the whole this number of the Transactions of the Nebraska State Medical Society is far above the average State Society publications. We could wish, however, that the writers would be a little more careful in the matter of spelling ("clo pot" does not stand for any drug in common use), and that the next volume will not show so much extraneous matter. Nothing so mars the value and elegance of an article as remarks seemingly intended to be rather funny. We also note a tendency in some of the articles towards sarcastic remarks. Happily these are faults that can be remedied. Elegance will often atone for a want of intrinsic value in an article, and inelegance has ruined many otherwise good papers.

A TREATISE ON EPIDEMIC CHOLERA AND ALLIED DISEASES. By A. B. PALMER, A.M., LL.D., Professor of Pathology, Practice of Medicine, and Clinical Medicine in the College of Medicine and Surgery in the University of Michigan, etc. Ann Arbor, Mich.: Register Publishing House. 1885.

This is a well printed octavo volume of 222 pages, embracing the consideration of Epidemic Cholera, Serous Diarrhœa, Cholera Morbus, and Cholera Infantum. The author devotes the first 67 pages to a brief historical statement of the progress of the chief epidemics of cholera in modern times, and a very interesting and impartial account of investigations in regard to the etiology of the disease up to the present time. While he gives to local meteorological and sanitary conditions an important if not controlling influence as necessary predisposing causes, he clearly favors the doctrine of a specific or essential cause, and that of an organic living germ. But after giving due weight to all the interesting microscopic researches of the last three or four years, he does not regard it as satisfactorily proved that the comma bacillus of Dr. Koch is the essential cause of epidemic cholera. The next 29 pages are occupied by a good résumé of the symptoms and morbid anatomy or pathological changes resulting from the progress of the disease. The next 43 pages contain a very full review of the current views concerning the Prophylaxis of Cholera. The comments of the author are characterized by sound discrimination and good sense The same good judgment, aided by personal experience, is seen in the full consideration which the author gives to the treatment of the disease, occupying 55 pages of the book The remaining 32 pages of the book are devoted to a very brief consideration of the diseases which the author calls allied to cholera This monograph is well worth a place in the library of every practitioner

THE FIELD AND LIMITATION OF THE OPERATIVE SURGERY OF THE BRAIN By JOHN B ROBERTS, A M, M D, Professor of Anatomy and Surgery in the Philadelphia Polyclinic, Surgeon to St Mary's Hospital 8vo, pp 80 Philadelphia P Blakiston, Son & Co 1885 Chicago W T Keener

This little volume, a reprint of the paper read by Dr Roberts at the last meeting of the American Surgical Association, is one of the most valuable monographs that has appeared in America for many years Its value consists in its brevity, its being concise and always to the point, and its wholesome disregard of traditions when experience shows that they are untrustworthy We have already expressed our opinion of this volume in the editorial columns of this week's issue of THE JOURNAL

ASSOCIATION ITEMS

INFORMATION OF IMPORTANCE TO ALL MEMBERS OF THE PROFESSION IN AMERICA

HOW TO OBTAIN MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION

MEMBERSHIP —Every one who attends an annual meeting of the Association as a delegate pays at that time five dollars, and thenceforward becomes a Permanent Member He continues as such so long as he remains in good standing in the body from which he was originally sent as a delegate As a Permanent Member, he must pay *Five Dollars Annually*, when notified by the Treasurer, whether he attends the meetings of the Association or not Payment of annual dues entitles him to receive the weekly JOURNAL of the Association for one year

MEMBERS BY APPLICATION are such as have not become Permanent Members in the manner above indicated, but apply to the Treasurer for membership, forwarding at the same time to him five dollars and the certificate of the President and Secretary of their State or local society, that they are in good standing in such society They pay five dollars annually thereafter, when notified by the Treasurer Members by application can join the Association at any time, and they receive regularly the weekly JOURNAL

WHEN DUES ARE PAYABLE —The annual dues from Permanent Members are payable to the Treasurer at the time of the annual meeting of the Association, or immediately thereafter The payment entitles the member to receive the JOURNAL for one year from the following July Payment for 1885, for example, entitles the member to the JOURNAL from July, 1885, to June, 1886, inclusive

As some of the members have not yet forwarded to the Treasurer their dues for 1885, they are urgently requested to do so at an early day Having entered upon another year of membership, they are morally and legally responsible to the Association for the payment of their annual dues, having already received for three months of the new year—1885—the JOURNAL of the Association

SUBSCRIPTIONS TO THE JOURNAL, from those who are not members of the Association, should be forwarded to the office of publication, 65 Randolph Street, Chicago, and not to the Treasurer, but *all payments of annual dues must be forwarded to the Treasurer, Lock Box 1274, Philadelphia*

DEATHS —When a member of the Association, who is in regular receipt of the JOURNAL, dies, his family or other representatives are requested to inform the Treasurer at once of the fact

PAYMENT OF DUES FOR PREVIOUS YEARS —As a few members of the Association are still in arrears for payment of dues for 1883 and 1884, they are requested to forward at once to the Treasurer the amounts for which they are indebted to the Association

TRANSACTIONS OF THE ASSOCIATION —These annual volumes, thirty-three in number, to 1882 inclusive, may still be obtained, with few exceptions, from the Treasurer, at reduced prices The Index to these volumes will be forwarded on receipt of *One Dollar* An opportunity is thus afforded to complete sets of these valuable publications, or to obtain important papers and works which are daily becoming scarce

RICHARD J DUNGLISON, M D, *Treasurer*
Lock Box 1274, Philadelphia, Pa

MISCELLANEOUS

THIRD ANNUAL MEETING OF THE OHIO STATE SANITARY ASSOCIATION, TO BE HELD IN COLUMBUS, FEB 24 AND 25, 1886

First Session, 9 30 A M Standard Time, Feb 24 —Reading of Minutes of Previous Meeting, Report of Standing Committees, Miscellaneous Business "The Relations of Christianity to Public Health," E R Eggleston, M D, Mt Vernon "Mistakes in School Architecture," Prof P W Search, Sidney "Defective Vision of Children, causes and management, with reference to pupils in our common schools," D R Silver, M D, Sidney "The necessities of Physical Education," A H Brundage, M D, Xenia

Second Session, 1 P M Standard Time —"The Plague of Streets," Judge Silas H Wright, Lancaster "The Climate of the Staked Plains, with particular reference to Midland Texas as a Health Resort," C A Lee Reed, M D, of Hamilton "The Climate of Columbus," Starling Loving, M D, of Columbus "What our Country People should know about Drainage and Sewerage," H M Fisher, M D, Akron "Introduction of Sanitary Science in Villages," T G Barnhill, M D, Finlay "Municipal Sanitation," C L Van Pelt, M D, Toledo

Third Session, 7 P M Standard Time —To be held in Senate Chamber, Capitol Address of Welcome, His Excellency, J B Foraker, Governor of Ohio President's Annual Address, "The Progress of Sanitary Science," Prof Edward Orton, LL D , Columbus "Food and its Relation to Disease," J H Herrick, M D , Cleveland "Artificial Feeding of Infants," W J Conklin, M D , Dayton Annual election of officers, selection of next place of meeting

Fourth Session, 9 00 A M Standard Time, Feb 25 —"Condensed Milk," F H Darby, M D , Morrow "The Meat Question," E T Nelson, Ph D Delaware "Who is Responsible for the Iniquities of the Third and Fourth Generations, and how can they be avoided?" R Harvey Reed, M D , Mansfield "Domestic Hygiene," G C Ashmun, M D , Cleveland "Sanitary Plumbing and House Drainage," James Allison, Cincinnati

Fifth Session, 1 P M Standard Time —"Tests for Impurities in Water available for Physicians' Use," Curtis C Howard, M C , Columbus "Purified as by Fire," G S Franklin, A M , M D , Chillicothe "Bovine and Humanized Virus and Supply of Virus," H J Sharp, M D , London "Cholera and its Prevention," D N Kinsman, Columbus Miscellaneous business, introduction of officers elect, appointment of standing committees, adjournment The headquarters of the Association will be held at the Neil House

Arrangements have been completed for the usual reduction of rates on all the railroads centering at Columbus, members will be returned at one cent a mile

EDWARD ORTON, LL D ,
President Columbus

R HARVEY REED, M D , Sec'y, Mansfield

The following named railroads will return all attending the meeting at *one third* the lowest unlimited fare, provided they apply to the Secretary, R Harvey Reed, M D , Mansfield, Ohio, within a week or ten days of the time of the meeting, and obtain the necessary certificate for the same, giving the name of the road and the station they desire to start from

Baltimore & Ohio, Chicago, St Louis & Pittsburgh, Cleveland, Columbus, Cincinnati & Indianapolis, Cleveland, Akron & Columbus, Columbus & Cincinnati Midland, Columbus, Hocking Valley & Toledo, Indiana, Bloomington & Western, Pittsburgh, Cincinnati & St Louis, Scioto Valley, together with all the important lines between Pittsburgh, Wheeling and Buffalo on the East, and Chicago and St Louis on the West

Return tickets will be issued at Columbus during the meeting at *one cent a mile*, on presentation of certificate from the Secretary, to all who come, and paid full fare over the Toledo & Ohio Central R'y

---

THE PLYMOUTH, PENNSYLVANIA, WATER COMPANY, is reaping a whirlwind of legal action Fourteen suits have been brought against it in the courts of Luzerne county by the relatives of those who died of typhoid fever last summer It is probable that many more will be brought It is claimed by the plaintiffs that the fever had its origin in contaminating material which reached the water supply from a cabin on the banks of a stream which feeds the Plymouth reservoirs The result of the trial will be looked for with interest, as it will be difficult to prove the trail of a typhoid fever germ Should the plaintiffs succeed in recovering judgment for damages against the company it would tax the resources of it to a severe point, but there would be a warning to other water companies They will have to learn that the public health of which they are so largely the conservators, is a trust so sacred that they must use the utmost precaution to prevent the conveyance of disease through water they supply The water shed must be made a subject for the keenest scrutiny

If the plaintiffs in these suits recover damages it it may be a warning to cities who control their own works, as well as to private water companies It is a question whether a municipal government is not as liable when it supplies impure water as it is when a leg is broken by imperfect sidewalks The care of the water-supply does not receive the attention from the public that it should, and a few successful suits for damages will show the public that it is within its power to demand pure water —*Sanitary News*, January 16, 1886

SANITARY CONVENTION AT HOWELL, MICHIGAN — The Michigan State Board of Health will hold a Sanitary Convention, at Howell, on March 3 and 4

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM JANUARY 30 1886, TO FEBRUARY 5 1886

Major Richard S Vickery, Surgeon, assigned to duty in connection with the Army and Navy Hospital at Hot Springs, Ark (S O 24, A G O , Jan 29, 1886)

First Lieut A R Chapin, Asst Surgeon, relieved from temporary duty at Ft Robinson, Neb and to rejoin his proper station, Ft Laramie, Wyo (S O No 11, Dept Platte, Feb 2, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING FEBRUARY 6 1886

Babin, H J , Surgeon, ordered to U S Str "Vandalia"

Dixon, W S , Surgeon, ordered to Marine Rendezvous, New York, to relieve Surgeon Babin

Whiting, Robert, P A Surgeon, ordered to U S Str "Vandalia"

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED FEBRUARY 6, 1886

Bennett, B H , Asst Surgeon, died at Detroit, Mich , Feb 3, 1886

Watkins, R B , Asst Surgeon, to proceed to Detroit, Mich , for duty Feb 3, 1886

Pettus, W J , Asst Surgeon, appointed an Assistant Surgeon Feb 5, 1886 Assigned to duty at New Orleans, La , Feb 6, 1886

CORRIGENDUM

In the article on 'Coryza' by Dr Geo N Monette JOURNAL of January 30 on 4th line of 1st paragraph read *heating houses* instead of treating processes In 3d paragraph read *moss factories* for 'mop factories The formula at end of article should read Bismuth subnit ℥i, Iodoform ʒij S Apply locally

ORIGINAL LECTURES.

IMPERFORATE URETHRA—EXCISION OF THE SUPERIOR MAXILLA—REMOVAL OF AN ENORMOUS HAIR MOLE FROM THE FOREHEAD

A Clinical Lecture Delivered at the Mercy Hospital, Chicago,

BY EDMUND ANDREWS, M D, LL D,
SURGEON TO THE HOSPITAL

We have here an unusual case This patient is only eight hours old, and is brought here because the urethra is imperforate Examining the end of the penis, the mucous membrane extends smooth and glistening over the end of the glans without a sign of an opening where the meatus should be However, if I compress it laterally so as to throw the surface into wrinkles, there is a slight depression at the proper place for a meatus Absence of the urethral canal is generally due to hypospadias, in which case the channel is not strictly non existent, but is only uncovered, from the non development of its floor, so that it is an open groove In this case, however, the parts are anatomically finished, so to speak, but the canal was either never formed or it has become obliterated in utero You will, however, bear in mind that just as the prepuce is sometimes found congenitally adherent to the glans, so we may suppose the walls of the urethra to be in some cases adherent to each other The surgical literature of this subject is exceedingly scanty, because the cases are few It is asserted by authors that new-born infants may die of the obstruction Obviously our duty is first to see whether this may be a mere adhesion of the urethral walls, capable of being separated If so, we may avoid any more serious operation You will notice incidentally that this patient, though only eight hours old, takes its ether exactly like an adult, and seems to require fully as much anæsthetic in proportion to its size as any older person

If I now take a large probe and sweep it along the fold which marks the site of the obliterated meatus, using some firmness of pressure, I find the parts separate under the effort, and a true meatus appears without a drop of blood being shed Selecting now a metallic sound somewhat conical at the tip, but still blunt, and of the size of No 2 of the English catheter scale, I press it into the meatus There is considerable resistance, but holding the glans firmly, and pressing the tip slowly on in the line where the urethra should be, I find the instrument gradually advancing, and no blood flows We seem to be separating adhesions rather than perforating tissues The force required is a good deal, and there is doubtless risk of making a false passage, but that will not be an irreparable evil Patiently advancing the instrument in this way, you see that now, at the depth of an inch and a quarter, the tip of the sound enters a normal urethral canal and then glides on without resistance into the bladder

Ordinary surgical text books scarcely refer to the possibility of this operation except when the occlusion is so thin as to be merely a septum across the passage I was led to attempt it in your presence by another case brought to me a few weeks ago, which seemed almost precisely like this The child was two days old No meatus could be found Moderate use of a probe made no headway Discouraged in trying to reopen the natural route, I went behind the scrotum and cut down upon the urethra at the middle of the perineum, thus giving a temporary outlet to the urine After a time, owing to the contraction of the wound in healing, the flow of urine was impeded and some force was required for its expulsion One day, to the surprise of all parties, the urine burst suddenly forth by the natural route, where there had been merely an adhesion of the urethral walls, which yielded to the pressure of the fluid behind the obstruction In all probability, had I been more persevering, I might have succeeded by the same operation which I have shown you to day

Excision of the Superior Maxilla —Six months ago this patient had a small tumor on the gum at the seat of the second upper molar tooth It was removed by a surgeon, but it has returned again It is now nearly the size of a hen's egg, extending backwards to the last molar, and inwards to the middle of the hard palate The growth is too soft to be an osteo sarcoma It is therefore either ordinary sarcoma, or a carcinoma As the glands of the neck are not perceptibly affected, there is hope that it may be sarcoma. No microscopic examination has been made, owing to the haste of the patient We will remove the growth

First comes the extraction of the canine tooth in front of the tumor, to make room for dividing the jaw, next we divide the upper lip in the middle, carry the incision around the alæ of the nose, and thence straight upwards The second incision passes from the angle of the mouth upwards and outwards, and then we dissect off the cheek from the tumor and draw it backwards The duct of Steno is entangled in the growth, and must be sacrificed Professor Marshall, who is present with his dental engine, now divides the arch of the jaw, the nasal process, and the anterior root of the zygoma With a thin chisel I divide the arch of the hard palate and seizing the growth with lion jaw forceps, readily bring it away You see that it fills the antrum, without adhering to it except at its posterior and outer border These places have therefore to be cleared out with the gouge-forceps and bone-scoop, and the cavity cauterized with crystalized chromic acid Replacing the cheek by the aid of suitable sutures, we will return the patient to bed The operation would have been more hopeful of permanent success had I seen the patient earlier

Hair Mole of the Forehead—This infant has an enormous hair mole extending from the transverse suture of the skull forwards and down over the whole right side of the forehead as far as to the upper border of the eyelid The hair upon it is exceedingly thick, and darker than that on other parts of the scalp However, the dark eyelashes show that, as the patient grows older, her hair will become black, and match that on the mole The skin on the centre of the growth is nearly black with pigment, and thick and wrinkled

The immense size of the mole renders it necessary to consider carefully the wisest way of dealing with it No amount of electrolysis of hair bulbs will answer here The following plan promises best First I dissect the skin of the mole from the top of the eyelid and carefully take it away up to the place where the brow ought to be We must now make an eyebrow, which I will do by cutting two arched incisions, leaving a strip of the mole between them to match the form and length of the brow on the opposite side As we do not know exactly how the contraction of the wound in healing will affect the form and position of the new brow, I make it a little wider than is ultimately needed, so that at a future time I shall have room to trim it to an exact correspondence with its fellow Now I will raise the skin above the arch, and dissect it off as high as is necessary to give her a forehead as high on this side as on the opposite part I will not remove that part of the mole embraced in the limits of the hairy scalp because, as she grows older, it will match the rest of her hair in color, and by dressing it low on the forehead she will be able to cover nearly the whole cicatrix from view

Having thus removed all that is necessary of the mole, I take from the outer side of the patient's thigh some thin shavings of skin and graft them upon the raw area, to assist the process of cicatrization, and improve the smoothness of the surface In grafting for this purpose we shave the grafts very thin, but apply them in large pieces, from half an inch to an inch in length, which often adhere very perfectly I have had them succeed an inch and a half in length The result in this case will be to remove a hideous deformity, and to restore the patient to a reasonable degree of comeliness, and perhaps even to some measure of positive beauty

THE TREATMENT OF CICATRICES IN THE COLLUM UTERI AND IN THE ROOF OF THE VAGINA[1]

BY A MARTIN, M D,
PROFESSOR IN THE BERLIN UNIVERSITY CORRESPONDING MEMBER OF THE GYNÆCOLOGICAL SOCIETY OF BOSTON

When, as long ago as 1862, and then more fully in 1874, Emmet indicated the operative treatment of rents in the cervix, which he considered as the sources of a whole series of gynecological maladies, these conditions had, up to this time, been very little observed They had been recognized as the cause of a relatively infrequent eversion (E Martin) or of an ectropium (Roser)

Emmet, on the other hand, regarded these rents as the sources of catarrhs of the cervix and of the the *corpus uteri* He emphasized the difficulty and even occasional impossibility of healing these catarrhs as long as the rent exists He further pointed out that these scars are the source of long continuing, ever-spreading irritation in the pelvis Finally, he very particularly insisted that such rents hinder the proper development of the uterus, if it become pregnant, and that in consequence, in a great number of cases, abortion is occasioned by them, and that many women who habitually abort suffer from rents in the cervix His proposition to heal these by operation, to perform trachelorraphy, excited very extraordinary notice at that time, since it occurred just when far more attention was being given to securing a widely-gaping aperture of the uterus, and the influence of the bilateral discussion was supreme

Emmet's propositions made progress among the Americans very rapidly, considering all things, in Europe, however, it was quite the contrary, and this operation was received very doubtfully, especially in Germany, although at that time operative gynecology was in a state of active development First there was opposed to the method of Emmet the general disinclination in Germany to favor operative interference with the *portio vaginalis* Then the attempts which were made to perform trachelorraphy were not seldom followed by imperfect results, the old cicatricial formation soon showed itself again more or less, or, on the other hand, there was formed a stenosis, an evil which just at that time it seemed to be a duty to zealously overcome by discissions

But even when, in Germany, the plastic operations on the *portio vaginalis* in great numbers were well received, and authors like Breisky, Spiegelberg, and Schroder, and among others the writer, busied themselves with this operation, the operation of Emmet remained a rarity Although, perhaps not least by the recommendation of amputation of the *portio vaginalis* which I warmly advised in 1878, at the meeting of German Physicians and Naturalists in Cassel, as imperatively indicated for wider fields of usefulness, gynecology was led so far that excision and amputation of the lips of the *os uteri* were undertaken not solely on account of chronic metritis and malignant degeneration, and in Germany this operation became very frequent, yet, notwithstanding all this, strangely enough Emmet's operation did not come into the class of the frequent gynecological procedures. This seems somewhat strange to American authors, especially if, after a prolonged sojourn in Germany, they observe our daily work, and this impression is fully expressed in the late work by Bigelow ("Berlin a Medical Centre").

---

[1] Read before the Boston Gynæcological Society by E W Cushing, M.D for the author, on December 10 1885

The cause of this peculiar state of things, however, is not at all that we do not recognize the importance of the cicatrices, that we regard the removal of the latter as anything difficult, or that the permanent results of our operative interference on the cervix were unsatisfactory, but the question was first considered whether the cervical rents are really the essential cause of the troubles on which Emmet insisted. The answer to this question is that we see cervical rents causing no symptoms too often to permit us to reply affirmatively. There are either, (1) *Catarrhal complications i e, affections of the mucous membrane*, or (2) *Peculiar and rare cicatricial formations*, which give importance to the cervical rents, and in such cases these should be attacked.

There is not the least doubt that we frequently find *catarrhs as complications of cervical rents*. But in such cases the catarrh is not dependent on the rent as such. It has either originated as an independent disease simultaneously with the injury of the cervix, or it has occurred there later. Doubtless, then, the symptoms of catarrh are much more prominent. The development of the glands of the area affected, and the increase in volume connected therewith, cause a protrusion of the diseased mucous membrane, the torn *os uteri* gapes, the cervical mucous membrane protrudes swollen, and with its hypersecretion and its hæmorrhages shows the well known and very typical appearance. The glandular new formation which we must recognize as the anatomical foundation of the erosions, according to C Ruge's very significant investigations, also keeps spreading on the surface of the rent of the cicatricial tissue here developed, as it may also cover the whole surface of the *portio vaginalis* (see plates LIX of E Martin's Hand Atlas, edit II of A Martin). Undoubtedly these complications resist obstinately any therapeutic measures. This form of catarrh can only be healed by a careful treatment, so that such patients must frequently suffer very severely, and become chronic invalids.

Emmet prefers to cure this affection of the mucous membrane by patient local treatment, and then performing trachelorraphy. In Germany it is generally preferred, as it appears, to use a more energetic treatment of the affection of the mucous membrane, after some trial of what treatment with medicaments for a reasonable period can accomplish. In such a case, however, there is no object in making also a trachelorraphy as such. For it is better to combine the excision of the mucous membrane with that of the cervical cicatrices, amputate the vaginal portion. By this means, as a rule, a very well shaped new *portio* will be formed in place of the torn, everted, diseased one. The majority of cases of amputation, according to the method of Hegar or Schroder, or as I do it as a rule, according to a plan combining both of these (see A Martin's Pathology, Treatment and Diseases of Women, 1885, p 285), gives a stump where, after completion of involution, very frequently the previous operation can be as little discovered as the alterations which led to the operation.

But in the few cases which heal thus typically there is moreover a proper aperture of the orifice with the lips of the *os uteri*, and a covering of flat epithelium. I have repeatedly endeavored to combine the typical Emmet's operation with excision of the diseased mucous membrane, and Schroder has also attempted this. For my part, however, I have given up this method completely, and in these cases I practice simply the typical amputation.

The cicatricial formation of rents in the cervix goes on and terminates in very different ways. It may so heal, corresponding to the quick changes in the cervical tissues, that scarcely any hardness and scarcely any cicatricial tissue can be distinguished, either by palpation or by the microscope. In other cases the cicatricial ramifications extend far beyond the immediate vicinity of the rent. Thence arises a displacement by contraction of the cervix, and also of the the body of the uterus, which may disturb the physiological position and shape of these parts of the uterus in connection with respiration, and motion, and fulness of the adjacent organs, in connection with their changes during menstruation and pregnancy.

Severe consequences occur when the rent has extended into the *parametrium*, reaching the base of broad ligament and the roof of the vagina, and drawing them out of shape, and, in a unilateral affection, drawing the uterus as far as the wall of the pelvis, or in cases of bilateral cicatricial formation, fixes it in the middle of the floor of the pelvis. Such fixation shows its presence at every jar of the body, at every change of position of the uterus. On this account severe distress is occasioned in almost all stages of the development of the malady, frequently defying treatment by medicaments. Operative interference is called for in these cases, and with such indications we practice it with the best results.

Cicatricial formation limited to the cervix is commonly treated by us by the typical trachelorraphy of Emmet. The results of this operation correspond to the good success which Emmet himself reports from it. When the mucous membrane is healthy a good scar is formed, which in case of subsequent pregnancy neither shows itself as a hinderance to the development of the body of the uterus or cervix, nor during delivery is found to be a weak spot, easily torn in the external os.

In cases of extension of the cicatrices in the roof of the vagina I am accustomed to use a somewhat different procedure. I first separate the cicatricial tissue of the roof of the vagina and of the floor of the pelvis from the cervix uteri, and excise the former completely from its environment. Then, if the cervical mucous membrane be healthy, I refresh the scar in the cervix, and here also I remove thoroughly all cicatricial tissue. Then the sutures are put in in such a way that the wound which was first round or even gaping parallel to the median line of the floor of the pelvis, is united to form a scar running transversely through the roof of the vagina This scar running transversely through the roof of the vagina terminates in the end of the cervical rent, the latter is closed either according to Emmet's plan, or, if there be at the same time disease of the mucous membrane, an amputation of the lips, excision of the erosions, and curetting of the mucous membrane of the uterine body is performed The dissection of the cicatrix from the cervix is made with a pointed two edged knife, and seems easy to perform when the parts are put properly on the stretch with the patient on her back and the vagina held well open by a Simon's speculum and Hegar's holders (see A Martin's "Diseases of Women," p 24, fig 15) The wound gapes, often large arteries spurt (branches of the uterine artery), and require quick action in controlling the hæmorrhage, or on the other hand temporary ligation at the sides The womb falls away from the wound by its own weight towards the median line in cases in which it has been distorted towards the side

After sewing up the wound a normal configuration of the roof of the vagina is generally attained Convalescence in the cases observed by me was attended by no difficulties The final result, however, was surprising in the completeness of the removal of the severe symptoms which had accompanied these cicatricial contractions One of my former assistants, Dr Czempin, has undertaken the presentation of the detailed histories of the cases observed by me, so that I can refer to this work, which will soon appear, concerning the various particulars of the cases

COCAINE AND OTHER ANODYNES IN OTOLOGY[1]

BY SETH S BISHOP, M D,

SURGEON TO THE ILLINOIS CHARITABLE EYE AND EAR INFIRMARY AND TO THE SOUTH SIDE FREE DISPENSARY

Before considering the newest and greatest remedy for annihilating pain, it will be both interesting and profitable to take a brief survey of the past history of anodyne aural therapeutics We sometimes look with pity on the semi intelligent, yet unavailing efforts of dumb animals to relieve themselves of great burdens or pains Similar sentiments are awakened by the scene which presents itself to our view as we look back into the darkness of the night of time, when the birth of the infant, Medicine, was attended only by the nurse of ignorance and the midwife of superstition In the presence of the great evil, pain, which all feared and none could conquer, the sufferer's friends looked on, helpless to relieve, or adding to the unfortunate's horror by crude, disgusting and aggravating remedies One can hardly believe the stories told of ancient practices until he reflects upon the superstitions of our own time Even now I know of a man who drives a thriving business by administering lobelia to every deluded mortal who applies to him for relief, and when the victim vomits, the mountebank exultingly points to the parts of liver which the patient is told he has ejected

In view of our own observations of human weakness and credulity, we should be prepared to look with consideration upon many of the worse than useless practices of the ancients To begin with Hippocrates a deceptive treatment has been imputed to him which he probably never practised He is cited as having recommended that "If any person have a pain in his ear, the physician should roll a bit of wool about his finger, and then pour some warm oil into the ear, and then, taking the wool in the hollow of his hand, he should hold it before the ear, in order to make the patient believe it has come out of it In order to make the deception complete, the wool should be at once thrown into the fire" The procedure is not consistent with what we know of Hippocrates, and moreover was not necessary, for he himself recommended the instillation of warm water into the ear for the relief of pain, and this treatment was sufficiently effective to preclude the necessity of practicing such a deception His warm water treatment is one commonly resorted to at this day, and has been advocated by numerous prominent authorities in medicine from his time to the present Apollonius recommended burned opium and castoreum Archigenes practiced venesection and warm baths to the ear Galen recommended warm wolf's milk or pepper mixed with old oil for earache from cold, but for inflammatory earache he used fat of geese and hens, and for severe pain, a mixture of opium, musk and white of egg, also castoreum, or a solution of opium in thickly cooked juice of fruit He took the precaution to use these remedies warm Cœlius Aurelianus employed leeches, cups, poultices and mustard plasters Marcellus's refined taste was pleased with nothing short of frog's fat, and, to cap the climax of æsthetic culture, Serapion spurns the aid of a being so primitive in the scale of creation as the frog, and soars to the loftiest pinnacle of perfection in the world's evolution, declaring that the fat of woman, and that fat only, cures earache His rule insists that the milk must be that of a woman who is nursing a female infant, if the patient be a boy

So familiar is the subject that but brief mention need be made of modern anodyne treatment as applied to the ear The popular domestic remedies are sweet oil, molasses, laudanum, roasted onion, glycerine and haarlem oil The exceptions to be taken to these are that the oils are likely to become rancid and irritating, and the glycerine and haarlem oil are too stimulating Moreover, the effects of most of these remedies are practically those of a poultice, namely warmth and moisture, and are generally to be deprecated Leeches afford more relief than any other topical treatment heretofore used by the profession Morphia sulphate in the form of Magendie's solution sometimes relieves I have been in the habit of prescribing it in 10 drop doses, warmed and instilled into the ear I have found it more effectual when combined with atropia, of the strength of 4 grains of the atropia to the ounce of Magendie's solution The warm breath, not blown, but breathed gently into the ear, with the open mouth close to the auricle, warm water and warm vapor, especially from chloroform, are sometimes very grateful, but chloroform should never be poured into the ear Warm tobacco smoke passed through a pledget of cotton placed lightly in the external meatus has proved very mitigating In many cases of acute otitis media which have come under my treatment before the discovery of cocaine, I have not been able to give patients such complete relief from pain as to secure sleep at night without exhibiting sedatives internally, such as chloral, bromide of sodium or potassium, and morphine

---

[1] Read before the Chicago Society of Ophthalmology and Otology February 9 1886

Cocaine is the last and best in the list, but the experience of those observers whose writings upon cocaine I have read, differs in so far from mine as that they seem to exclude the skin from its field of utility, whereas I have often applied it to cutaneous surfaces with the happiest results To be more explicit I have repeatedly employed it in aural diseases in which an acute inflammation was limited to the middle ear, when inspection disclosed the drum head in its integrity, the external meatus not being involved, and the tympanic pain was intense When I began using cocaine in these cases I employed a four per cent solution of the hydrochlorate I brought no other pain alleviator to my aid, but relied entirely on the new drug for relief My practice has been to warm half a dozen drops of the solution and instil into the ear, with the patient's head inclined to the opposite shoulder He is requested to maintain this position for five minutes, and before the expiration of that time the pain is invariably assuaged Usually not more than one or two minutes elapse before I inquire if the pain has ceased, and rarely has it happened that an affirmative answer was not returned before the expiration of two minutes If it be asked how it happens that pain produced by pressure on the nerves in the middle ear is relieved by a local anæsthetic in the external ear, with a layer of skin and connective tissue interposed between the medicine and the diseased membrane, I reply that it is the result of endosmosis

In acute otitis media the tympanic cavity contains mucus, if not muco-pus, by the time a patient seeks the aid of a physician Thus we have given a membrane intervening between fluids of differing densities, and a form of molecular attraction allied to that of adhesion, with the result of a rapid flow of the thinner fluid through the interposed membrana tympani, to become equably diffused in the thicker fluid contents of the middle ear This passage of the cocaine solution through the drum head is certainly a rapid one, for there is no room for doubt that it reaches the paining nerves in less than two minutes after impinging upon the membrane This rapidity of action does not appear so wonderful to one who makes a practice of applying the remedy to mucous surfaces, for almost immediately upon its touching the nasal or faucial mucous membrane the benumbing effect is realized The result for which I was least prepared was that patients usually reported that there was no return of the pain I was led by my experience with cocaine in hay fever and coryza to expect a recurrence of the symptoms at the expiration of an hour and a half or two hours

If I may be allowed to digress for a moment I will mention several facts of interest, though somewhat irrelevant By treating a carious tooth with cocaine I have dissipated a reflex earache, while curing the toothache I have operated on squint eyes under cocaine anæsthesia without producing any pain However, it is not a suitable substitute for atropia to relieve pain, for its continuous application to the cornea seems to produce opacities It dilates the pupil when used locally, whereas in toxic doses internally it is said to produce contraction On account of its primary inhibitory action on blood-vessels, little hæmorrhage occurs during an operation under its effects, but its secondary dilative action permits as free bleeding afterwards as though the remedy had not been employed I have prescribed a two per cent cocaine ointment in severe cases of thrush with the result of procuring sleep

There is still another particular in which my experience appears to have been unique When I have found it necessary to apply a counter irritant over the mastoid process and below the auricle, I have painted the parts with the essential oil of mustard, and allowed it to remain until the stage of vesication approached and the patient complained bitterly of pain Then the cocaine solution was painted thoroughly over the reddened surface, and in a few minutes the burning pain ceased Hence the question arises why may we not be able to control the pain of burned surfaces in the same way, and to relieve the burning sensation of erysipelatous inflammation, the itching and burning of eczema and kindred affections? I have frequently employed this remedy in painful inflammations of the middle ear when perforations of the membrana tympani have existed, but I cannot say that the results were more signal than in those cases in which perforation had not occurred I recall a case in which I made a crucial test of the efficacy of this new anæsthetic It has been my practice, after removing polypi, to cauterize the sites of attachments with mono chloracetic acid, to preclude a reproduction of those growths I have had under treatment a case of chronic suppurative inflammation of both middle ears, of thirty years' duration In either ear was a large fibrous polypus, in one it was so large as to extend beyond the opening of the external meatus The patient could hear nothing with the worse ear, and very imperfectly with the other, even when aided by a capacious ear trumpet I removed one polypus and cauterized its base, having ready a four per cent solution of cocaine in a medicine dropper When the pain from the acid reached its height the cocaine was dropped upon the burning tissue, and in a moment the pain distorted countenance was transformed into a happy expression of gratitude When I operated on the other ear I took the precaution of applying the cocaine thoroughly before resorting to the cautery The patient experienced no pain, and was loth to believe that the same treatment had been given

It will be readily understood, after reflection upon the mode of entrance of cocaine in solution through the drum head into the middle ear, why the solution and not an ointment should be employed, but the ointment of the same strength is better adapted to the treatment of furuncles, for it will remain longer in contact with the parts A powder which I employ in treating the respiratory passages may be used to cover furuncles, or to insufflate the middle ear when a perforation of the drum head is present The powder consists of six (6) parts of cocaine hydrochlorate and ninety four (94) parts of sugar of milk This makes an impalpable powder which will readily pass with a column of air impelled through a perforation in the drum head The instrument which I devised for insufflating cavities with powder is especially useful in this instance It consists of a stout bottle three inches high and two inches in diameter, with a soft rubber stopper There are two perforations extending vertically through the stopper, through which pass two vulcanite tubes The latter pass downward through the stopper, but do not extend below its under surface Above the stopper the tubes are bent in a curve so that their extremities point at right angles to their vertical portions To one of these extremities is attached a rubber tube and bulb The bulb contains a valve of soft rubber at either end, to prevent a regurgitation of the column of air sent into the bottle of powder, and a consequent dusting of the operator's clothing By varying the force with which the bulb is compressed one may project a small or large quantity of the powder into the ear at pleasure

There are other important effects of cocaine on mucous surfaces than that already mentioned After it has been in contact with mucous membrane about ten minutes, the mucous tissue presents a pale and contracted appearance, even if it were previously red, swelled and painful, as it is in thrush, coryza and hay fever This, together with the anæsthetic effect, may be taken advantage of in catheterism of patients in whom the inferior meatus is constricted, and lined with a hypersensitive membrane In those cases the powder is more conveniently applied than the solution, and the six per cent powder is susceptible of more general application than any other In mild cases of pain and hyperæsthesia I have found the two per cent preparation quite satisfactory

Although the primary effect of cocaine on mucous tissue is to cause paleness and shrinking of the membrane, there is a secondary effect which I have observed repeatedly, but which I have never seen mentioned by any other writer If the parts have been thoroughly anæsthetized, and especially if they have been kept in that condition for a number of hours by renewed applications of the remedy, there follows a considerable swelling of the membrane, which persists with more or less constancy for a day or two after the applications have been discontinued, and the subsequent hyperæsthesia may be found to be augmented

However, it must be conceded that cocaine has demonstrated itself to be the most important local anæsthetic that medical science has yet discovered But a few months old, in a therapeutic sense, its brilliancy of achievement has flashed like a meteor over the whole medical world So deep an impression has it made on suffering humanity that it has rapidly passed beyond the conservative control of professional men The laity grasps at anything that promises to be a boon—a panacea for all aches and pains An indiscriminate use results—an actual abuse of a remedy as potent for evil as it is powerful for good Already the cocaine habit has supplanted the morphine, alcohol or chloral habit A step in the right direction has been taken by the profession of New York, by the preparation of a bill for the Legislature, to place cocaine on the list of poisons to be sold only on physicians' prescriptions

Cocaine poisoning has repeatedly occurred, and in the midst of our own ranks, impaired health and temporary insanity are attributed to the excessive use of this drug So, while lauding its merits, let us manifest a just appreciation of its dangers, and erect lighthouses of caution with the victims who have fallen prey to its direful power But the history of medicine is like the history of men The greater the man, the grosser the abuse The better the drug, the worse is its misuse A note of timely warning should be sounded, and the duty of the conscientious physician done, for although one cannot be the keeper of his patients' wills, he should be a guardian of their health and morals

THE FLAP EXTRACTION OF SENILE CATARACT

BY J W THOMPSON, M D ,

OF ST PAUL, MINNESOTA

Of all the methods of dealing with senile cataract that have at various times been detailed and advocated by different authors, the upper flap with an iridectomy has been attended with more uniform and favorable results than any other The flap extraction was first practiced without the removal of a segment of the iris The results thus obtained were superior to those by any of the other methods that had been previously practiced Statistics show that about ten per cent of the cases thus treated were lost Mooren, of Dusseldorf, in 1862 proposed the following method He first did a very free iridectomy, removing a large segment of the iris He then allowed the eye fully to recover, waiting perhaps three or six months as the case might require, when he made the ordinary flap upwards and extracted the lens This method has to day many advocates, and its advocacy is founded upon sound principles Small insults can be tolerated better than great ones It divides the operation into two equal parts, and likewise divides the danger to the organ The flap extraction is not, however, without its dangers

There may be diffused or defined suppuration of the cornea, or iritis, and in extreme cases of danger there may be not only iritis and suppuration of the cornea in conjunction, but every structure of the organ may be seized with an active form of inflammation which, with the unfavorable surroundings, would terminate in suppuration and its entire destruction Iridectomy is powerless to protect against the calam ity of diffused suppuration of the cornea, while it might exercise a good influence in the event of a threatened defined inflammation. It does, however, give a high degree of immunity from iritis. In every flap extraction accompanied with an iridectomy at the same time, iritis is one of the chief dangers to be anticipated. It is no exaggeration to say that nine tenths of the failures that occur in flap extraction when the iridectomy is done at the same time, have their origin in iritis.

When the iris is wounded and left without its natural lens support it is very much more susceptible to acute inflammatory action. Hence, when the iridectomy is done as a preliminary step the iris is left with its natural lens support and is placed under the most favorable circumstances for recovery, and thus the danger from iritis is almost if not quite removed when the subsequent flap is made for the removal of the lens. If the final operation be dextrously done the iris is but little disturbed. The upward flap with the iridectomy, of course, in the same direction, is preferable to the downward direction for two reasons. 1. The upper lid furnishes an excellent support to the flap and holds the corneal edges in close coaptation, a circumstance both essential and desirable for a rapid union of the parts. 2. The artificial pupil is covered by the upper lid, which not only obscures the deformity but prevents that disagreeable dazzling, an unavoidable concomitant when the pupil is made in any other direction. This method, however, of treating senile cataract has been objected to by many on the ground that the patient is subjected to the anxiety of two separate and distinct operations. This objection is, I think, in a very great measure overcome since the introduction of the use of cocaine as an anæsthetic in ophthalmic surgery.

When this agent is properly employed both the operations are rendered almost or quite painless. By way of illustration I had occasion to do an iridectomy a short time since, and after completing the operation the patient in a very complacent manner asked me if I would soon be ready to begin. When the first operation has thus been demonstrated to the patient to be painless while consciousness is undisturbed, the subsequent one is in a very great degree robbed of its anxiety. But it has been urged by some as a serious objection against the use of cocaine in the cataract operation that it diminishes the tension of the globe, thereby increasing the difficulty of the operation. This is another hair-splitting objection. Can any one tell why it should lessen the *tension* any more than atropine? Is it a fact that it does? It is a well recognized practice and I think a very good one, to drop into the eye a solution of atropine of sufficient strength to procure as wide a dilatation of the pupil as possible before operating. I have used both hundreds of times and have never been able to discover that the one diminished the tension any more than the other. Admitting for the sake of argument that cocaine is the more relaxing of the two, I think that the slight inconvenience to the operator is compensated in a twofold ratio. 1. It renders the operation almost or quite bloodless, and thus prevents that occasional and disagreeable occurrence, a chamber partially or perhaps wholly filled with blood from a bleeding iris. 2. The diminished tension lessens the chances of rupturing the posterior capsule, which might allow the vitreous to come forwards into the chambers, a circumstance highly to be deprecated.

The method of making the flap has been regulated by laws which give the greatest possible space for the exit of the lense with the least possible division of the structures involved. In entering the anterior chamber the point of the knife is directed towards the centre of the globe. As soon as the point has fairly entered the chamber the handle of the knife is carried backwards until the blade is parallel with the plane of the iris. In this position the point is shoved along till it passes the centre of the pupil. The handle of the knife is now depressed till the point reaches a position directly opposite the place of entrance, where it is made to transfix the cornea. The blade is still parallel to the plane of the iris, with its cutting edge directed upwards. Thus the blade, being parallel with the plane of the iris and the edge directed upwards with a gentle sawing motion, is made to divide the cornea till its extreme upper segment is reached. The edge is then turned upwards sufficiently to bring the plane of the knife perpendicular with the axis of the globe. In this direction divide the corneal substance till the conjunctiva is reached. From this point carry the edge between the conjunctiva and the sclerotic a half a line in distance, and then cut through the conjunctiva. This makes a little conjunctival flap which can be easily adjusted after the removal of the lens. The great vitality and vascularity of the conjunctiva render its union so rapid that a good support is made to its corneal edges.

A word in reference to lacerating the lens capsule may at this place be apropos. Instead of using the ordinary pricker or cystitome for incising the capsule of the lens I have, with very satisfactory success in a large number of cases, adopted a very different method. I employ the point of a Grafe cataract knife to split the upper segment of the capsule large enough to permit the exit of the lens. By this method the lens substance is shelled out of the capsule and the cortical substance is left behind where it is out of harm's way. At least that part of it is left which would otherwise float about in the chamber and come in contact with the iris and perhaps ciliary bodies, and thus act like a foreign substance and be a dangerous source of irritation. When it is left incarcerated in the capsule it is equally as readily absorbed, since the aqueous has free access to it.

The location of the flap has been much discussed at one time and another. Some advocate its location entirely in the sclerotic, others in the sclero corneal junction, while there are many who think it should be made wholly in the cornea. The reason assigned for making it entirely in the sclerotic is that this tissue heals more readily than the cornea. Experience has, however, proven this to be a fallacy. Admitting, for the sake of argument that there is a slight difference in favor of the sclerotic, it would be unquestionably more than overbalanced by going as near the ciliary region as is necessary to make the flap wholly in this tissue This is the dangerous region of the eye, and the wider one steers of it in any operation the less is the result jeopardized The sclero-corneal flap is, in a diminished degree, however, open to the same objections The reason, therefore, for making it wholly in the cornea is twofold 1 It is farther removed from the ciliary region, and 2 The experience of such men as the late Mr *Critchett, of London, confirms the assertion that this* tissue unites more readily than the sclerotic

There are some objective symptoms that are valuable in giving a prognosis as to the result to be obtained by the flap extraction The first of these is the condition of the pupil whether it be active or sluggish, whether it respond promptly to the influence of light and shade, and atropine The latter condition is the more favorable one, from the fact that the stiff, thick, sluggish iris is predisposed to iritis The muscle is partially deprived of its animal matter, its fibres are infiltrated with disorganized material which deprives it of its normal elasticity and power to resist inflammatory action Its vitality is lowered, and consequently its power to resist mechanical injury diminished Therefore an active pupil can in truth be said to be a favorable prognostic symptom Again, the flap operation should not be attempted when there is the slightest evidence of conjunctivitis Cure this first Neither the patient nor the physician can afford to disregard this one, little, important point The drainage apparatus of the eye should also be carefully inspected

When the extraction of the lens is completed, a collapse of the capsule is another favorable indication The reason for this is twofold 1 It is an evidence that the posterior capsule is intact, or at least that the vitreous has not been disturbed, and 2 That the cornea is in a healthy condition, as evidenced by its pliability These are some of the considerations that should govern one in giving an opinion as to the probable results of a flap extraction

Again, an extraction should not be done when there is any prevailing epidemic, such as cholera or any of the exanthemata The depressing influences of these upon the mind of the patient disarms, as it were, the physical forces, and thus, in the unguarded moments of nature, golden opportunities are thrown away and forever lost It is so unlike many other operations, since the slightest error may turn the tide of success and leave the patient in total darkness

The general condition of the patient's health should also receive the most careful attention In short, the more carefully every detail, be it ever so small, is considered, the greater will be the chances of success As the whole is composed of parts, so little ills combine to establish a morbid condition which may defeat the desired result The experience of the past few years has also wrought some very valuable changes in the after-treatment of flap extraction When the edges of the flap are brought into close contact with each other and all coagula carefully removed, the present practice is to close the eye, cover it with a circular piece of soft linen, and then fill up the orbital cavity with little pieces of carbolized cotton, equally distributed Before applying the bandage, place a few pieces of the cotton around the orbit in such a manner as to prevent too much pressure directly upon the eyeball I prefer a flannel roller, which should be passed around the head three or four times in such a manner as to cover the eye and give an equal support to the entire surface of the globe

The other eye should be covered as well, in order to insure perfect rest to its fellow The bandage and cotton should be changed every twenty four hours If all goes well, this is the only dressing that will be required The old practice of applying cold water dressing has been entirely discarded It washes away the corneal cementum and embarrasses the reparative process There are numerous emergencies that may arise, but to detail them here, with the various methods of treatment, would extend far beyond the limits assigned to this paper Before dismissing the subject, however, permit me to ask of my readers for any innovations on the established order of things contained herein, a resistance that loves to be reasonable rather than energetic

309 Wabasha St , St Paul, Minn

SOME PECULIAR CASES OF EPIDEMIC FEVER OCCURRING IN TOULON, ILLINOIS[1]

BY W T HALL, M D,
OF TOULON, ILLINOIS

The purpose of this paper is to give a history of a peculiar epidemic which recently occurred in Toulon, Stark Co , Illinois This history may, however, be prefaced by saying that Toulon is well watered, very few of the wells being influenced by surface water, and no cases of the epidemic occurred in the part of the town where the wells are so influenced The natural drainage is far superior to that of most towns, and the sewerage has been carefully, scientifically and methodically cared for

Having lived in the town for forty years, having known all the epidemics of the town, and having only known of one family before in which typhoid fever originated and went through the whole family, I was at a loss to account for this abrupt appearance, and persistent protraction The number of cases thus far have been twenty six, the ages ranging from 11 to 67 years These have all been typical, well marked cases, though many others in the different families in which the disease has appeared have had some of the premonitory symptoms, but no further development

Nineteen of these cases came under my care, and in speaking of this epidemic I will only describe those under my own personal observation The first patient was taken sick July 27, 1885, and they have continued to make their appearance up to the present writing (November 9) The premonitory symptoms for the first ten days are those of typhoid fever, with the exception of more lassitude and more catarrhal trouble On the eleventh day in thirteen of these cases, and in the remainder on the twelfth day, de veloped the trouble which was to be predominant through the course of illness. Four cases were pronounced typhoid with well developed catarrhal fever as a complication. The only symptom lacking in these cases was the typhoid eruption, and that was lacking in all the cases. One of the peculiarities of this epidemic has been that no two cases in the same family have been exactly alike. For instance, I have treated three cases in two families. In the one, the typhoid element was predominant, in the second the malarial, and in the third the catarrhal. The ringing in the ears was present in all, was the first symptom complained of and lasted through the whole course, increasing in severity, so that by the seventh day it became so pronounced that it was almost impossible to make the patients understand anything said to them. The tongue in two cases was red and glossy, in three brown, in the remainder white and flabby. In fourteen tremulous, and in seven pointed.

---

[1] Read before the Military Tract Medical Society, on November 10 1885

The stomach was exceeeingly irritable in sixteen of the cases, this commencing on the fifth or sixth day, and lasting from twenty to twenty five days. The ejected matter was bilious all through the course. The liver was engorged, and tender over the right lobe, in every case forming one of the first complaints, and lasting to its termination. Hæmorrhage of the bowels occurred in four cases very severely, in one case mild. It occurred in two cases on the fourteenth day, in one on the twelfth, and in one on the twenty-ninth. In all of these cases the red tongue and tenderness in the iliac region were absent.

The hæmorrhage lasted in one case four days, in one six, in one three, and in one one day. The last passage in all the cases resembled beef's liver, both in color and consistency, more than anything to which I can compare it, there were no clots, but a congealed mass. There was hæmaturia in three cases, coming on from the eleventh to the thirteenth day, but it never occurred in a patient who had hæmorrhage from the bowels.

The parotid gland was enlarged in six cases on both sides, in five on one side. The enlargement commenced on the fifteenth day in all the cases save one, and in that on the eighteenth day. Abscess formed in but one case, and I opened that on the fiftieth day, no pus being present until that time.

There were convulsions in three cases, in two on the fourteenth and one on the seventeenth day. In two I attributed them to reflex action from the bladder, which I shall describe farther on, and in one to hereditary tendency to chorea. In the two of reflex action recovery took place, in the choreic, death was the result. One had two convulsions, one five, and the fatal case nine.

There was delirium in four cases, it being the delirium of typhus rather than of typhoid fever. The remainder would answer the questions coherently, yet upon recovery, the twenty-five or thirty days' period of illness was a perfect blank. There was no muttering, no wandering except in the four cases mentioned, and they were of that wild uncontrollable type, with the ringing metallic voice found in the delirium of typhus fever.

The temperature was an even one, with nothing of the zigzag found in typhoid fever. In seventeen cases it ranged from 100° to 100.5° F., in one 104°, and in one 105°. So the antipyretic treatment with quinia was indicated in only two cases. The temperature in the seventeen cases did not vary half a degree at any time for twenty five days.

Syncope occurred in three cases, in one on the seventeenth, one on the fourteenth, and one on the twenty second day, in one of the cases lasting fourteen hours.

Epistaxis took place in all the cases from the second to the third day. In the most of them it was mild and subsided after two or three days. In two it was severe and came on every few hours for twenty three days.

The catarrhal complications were not only present in all the cases, but caused by far the most pain, and were the hardest to control. Some of the cases would be upon the bed pan six hours out of the twenty four, and one of them told me who had had three children that she suffered more each time in passing water than she had done in labor.

The urine was scanty, highly colored, and very offensive, frequently not over a teaspoonful after an hour or two of hard straining. It was in the two cases of convulsions I have referred to as being caused by reflex action, as both cases went into convulsions while passing water.

Diarrhœa was present in all the cases except one, and that was the one that had the hæmorrhage from the bowels only one day. The discharges were bilious, and the most offensive I ever experienced.

All the patients had a peculiar smell, unlike any odor with which I am acquainted, but just as pronounced as is that of measles and small-pox. In fact, by the second day, I could tell by the smell those coming down with this trouble. The night sweats were severe in only two cases, but occurred in eleven. I omitted to state that the catarrhal affection extended along the whole track of the nose, the Eustachian tubes, and the ear. The fatal case died on the seventeenth day. The eighteen cases that recovered were bedfast from twenty-three to sixty days.

These, I believe, are all the points of interest, save a few words as to the treatment. The first patients presenting themselves with a brown dirty tongue, and many of the symptoms of a bilious attack, I gave them calomel and jalap in powder, 10 grains each, followed in six hours by a Seidlitz powder. But I soon found that I had cases that were going to be protracted, and that I had to guard well my patients' strength, and that persuasion rather than coercion should be followed. I found that 2 grains of calomel, with 3 grains of bicarbonate of soda every second night, was preferable, with 5 grain doses of bismuth through the day. I gave quinine in from 5 to 10-grain doses every two hours through the whole course of the disease, except in the two cases in which I wanted the antipyretic effect, in those I gave to one 25 and the other 40 grains, in the evening, for four days, at which time the temperature came down to 101.5° F. and remained so until recovery. Instead of aural symptoms from the large doses of quinine, the hearing became better, convincing me that a malarial poison was at the bottom of all these peculiar phenomena, else there would not be such a tolerance for the drug Turpentine, so useful when the tongue is red and glossy, was not admissible at all, as the only cases to which I gave it had strangury in from six to nine hours after administering it It would produce that trouble even in 5 drop doses I found that balsam of copaiba and cubebs in capsules gave the only relief for the bladder trouble I gave them in capsules, as the stomach would reject them in liquid form

I gave ergotine for the hæmorrhage from the bowels, Dover's powder and camphor for the delirium, atropia for the sweating, bromide of potassium and bromide of ammonium for the convulsions, 10 grain doses of the potash, and 5 of the ammonium, every half-hour until the convulsive movements ceased For the syncope I gave the carbonate of ammonia and tincture of digitalis These drugs, of course, were given as indicated, while the quinia was never omitted until convalescence was fully established, and was then given for a week or more at lengthened intervals

COCAINE IN HAY FEVER

BY E FLETCHER INGALS, M D,

PROFESSOR OF LARYNGOLOGY IN RUSH MEDICAL COLLEGE AND PROFESSOR OF DISEASES OF THE THROAT AND CHEST IN THE WOMAN'S MEDICAL COLLEGE CHICAGO

In the issue of THE JOURNAL for February 6 appeared the report of a lecture on the above topic by Dr S S Bishop, in which cocaine is highly recommended for the relief of hay fever The writer also mentions the fact that the drug sometimes causes unpleasant effects and that it cannot be considered curative

In addition to what he has said of it I wish to call attention to an effect which I have frequently observed, viz Continued use of the drug renders it necessary for the patient to take more and more of it for relief, and finally the constant stimulation of the sympathetic nerves in the nasal tract causes paresis, with resulting swelling of the turbinated bodies, which may at length permanently obstruct the naris Dr Bishop states that no cure for the affection has been heretofore discovered, but in this I am confident he has made a mistake The surgical treatment which he says is "too recent to have afforded permanent results" is as certainly entitled to the distinction of being a curative procedure as quinine is entitled to that of being curative for intermittent fever It has now been in use for four years, and the cases thoroughly treated by it at first are still free from the disease I have treated many patients in this way, and every one of them in whom the treatment was complete escaped the attack last summer The writer suggests that the treatment may cause spasmodic asthma In this I fully agree with him, as anything which causes closure of the naris may cause asthma, but it is the exception with patients treated by this method, just as it is the exception for people to have asthma in whom the nares are occluded from other causes

It is true, also, that in his own case two applications of the galvano-cautery were followed by asthma, and that they did not cure the hay fever Two applications of the cautery never could cure the hay fever, for when the nasal mucous membrane is sensitive enough to cause the disease there is as much of it involved as can be safely cauterized in fifteen or twenty sittings

We must remember that in both nasal cavities there is an area of mucous membrane of not less than sixteen square inches, and sometimes half of this is involved, at the same time not more than one fourth or at most one half a square inch of surface should be cauterized at any sitting, and the last amount will be well borne only in exceptional cases

In conclusion I wish to reiterate my belief in the value of cocaine for the relief of hay fever, in which disease I think I was first to use it, but I wish also to direct attention to the ill effects which may follow its protracted use, in order that physicians may caution their patients against using more than is absolutely necessary

I wish, also, to assure the profession that they have in the surgical treatment a cure for the disease which may be relied on in at least nine cases out of ten

64 State St, Chicago, Feb 9, 1886

MEDICAL PROGRESS

DIGESTION ITS PHYSIOLOGY AND PATHOLOGY — PROFESSOR EWALD AND DR J BOAS publish (*Virchow's Archiv*, Bd ci, Heft 2) the results of a number of valuable experiments they have made on inmates of the Woman's Infirmary in reference to the physiology and pathology of the digestive act One of the inmates was especially suited for this purpose She was a young woman with a peculiar neurosis of the stomach, of an hysterical nature, in whom for the past six years vomiting had occurred spontaneously almost immediately on the ingestion of fluids, and from two to three hours after partaking of a solid meal Her appetite was normal and her general health good, and she increased in weight while in the hospital Repeated examinations showed the process of digestion to be normal Inspection of the contents of the stomach when she was fasting showed (1) that they were constantly free from aliment, (2) that as a rule the reaction was neutral, in a few cases slightly acid, (3) that neither free hydrochloric acid nor lactic acid was present, (4) that peptone was constantly absent This is in direct contradiction to what Schultz has recently stated—that the stomach, fasting, has its contents strongly acid To meet the objection that the act of vomiting might influence the chemical changes, experiments with the siphon stomach tube were made on other inmates of the hospital in whom there were no disturbances of digestion These gave results identical with those in the case of Seeger—the patient subject to vomiting By employing certain reagents, the observers were enabled to separate lactic acid from hydrochloric acid, and detect their presence respectively in the contents of the stomach On giving Seeger 60 grains of white bread, it was found that in ten minutes afterward the contents of the stomach gave a slight lactic acid reaction The reaction increased in intensity for thirty or forty minutes, after which the lactic acid began to disappear and free hydrochloric acid took its place As the latter increased, the lactic acid diminished, until a a stage was reached when it completely vanished They would therefore divide the process of digestion into three stages—the first, in which lactic acid is present but no hydrochloric acid, the second, or intermediate, in which the lactic acid reaches its acme and hydrochloric acid first appears, the third, in which the lactic acid rapidly disappears while the hydrochloric acid increases in quantity On giving the patient pieces of thin sliced meat, the same three stages were observed, but the duration of each was longer than when white bread was given The first occupied fifty minutes, digestion as yet had made but little progress, the meat fragments were still of a fleshy red color, and the transverse straiæ were quite distinct The intermediate stage extended to ninety minutes after the meat had been eaten Even yet the digestion had not made much progress, the reagents showing the presence of sarco lactic acid and a slight amount of hydrochloric acid In the third stage (ninety to a hundred and twenty minutes) no sarco lactic or lactic acid could be detected, while free hydrochloric acid existed in abundance With a fish diet exactly similar results were obtained Very convincing evidence that the lactic acid is a product of fermentation of the food taken, and not a secretion from the stomach, was afforded by the experiments of giving the patient egg albumen alone The examination of the stomach contents did not show the presence of lactic acid in any of the stages Quite different were the results when potatoes, which are a great producer of this acid, were given Lactic acid was detected as early as ten minutes after eating, and persisted for a long time To fully comprehend the strength of the position they take in reference to the rôle played by lactic acid in digestion, another of their experiments must be related They allowed the patient to masticate 30 grammes of thin sliced meat and 20 grammes of white bread These were divided into five equal portions, one portion of each was treated with a 0 3 per cent solution of hydrochloric acid They were all put into the incubation oven for three hours at a temperature of 40° C , then left for seventeen hours at the temperature of the room There were thus four portions 1, 15 grammes of thin sliced meat, 2, 15 grammes of thin sliced meat plus 10 c cm of a 0 3 per cent solution of hydrochloric acid, 3, 10 grammes of white bread, 4, 10 grammes of white bread plus 10 c cm of the 0 3 per cent solution of hydrochloric acid These, on being tested, gave the following results 1, strong lactic acid reaction, no peptones, no sugar, 2, also strong lactic acid reaction and slight peptone reaction, 3, strong lactic acid reaction, 4, no lactic acid reaction A strong antagonism, they say, exists between the two acids If the digestive act is interfered with in any way, the lactic acid stage is lengthened in duration An interesting fact in connection with this was noticed in the patient Seeger During menstruation the period of digestion was prolonged, and so was that of the lactic acid Delayed digestion would, therefore, go hand in hand with the persistence of that acid in the stomach Therapeutically, the authors would only say this much in this paper that the results of their experiments place the selected diet-tables in a new light All those articles of food considered difficult of digestion are known to be great lactic acid producers The addition of hydrochloric acid not only supplies the essential acid of digestion to the stomach, but causes the lactic acid to disappear, thus removing a factor of delayed or prolonged digestion The authors are still continuing their investigations, and promise to make known the further results in a future paper —*New York Medical Journal*, February 6, 1886

THE STRUCTURE OF THE PANCREAS —MR VASILY SOKOLOFF, soliciting the degree of "magister of veterinary sciences," selected for his inaugural work the study of the minute structure of the pancreas during its rest and action (*St Petersburg Inaugural Dissertation*, 1883, pp 48, and the *Arkhiv Veterinarnykh Nauk*, Dec 1883) The structure of the quiescent gland was examined in dogs, cats, rabbits, horses, cows, sheep and pigs To study the alterations taking place in the gland during its physiological action, he killed dogs, cats and rabbits at certain periods (4, 5, 7, 10, 15, 20, 40 hours) after the ingestion of food or after a subcutaneous injection of pilocarpine The specimens were hardened in chromic acid, spirit of wine, tincture of iodine, osmic acid, muriate of gold, and Muller's fluid, and then stained with hæmotoxylin or picrocarmine The results of these investigations (carried out in Professor F N Zavarykin's laboratory) are summed up by the author as follows

1 The changes in the structure of the pancreas during its action, show that the process which takes place in it is identical with that observed in other glands of similar anatomical structure and function (salivary, pepsine glands, etc)

2 During its physiological rest, the secretory cells become granular and increase in their bulk ("as if swell"), their homogeneous zone being considerably diminished, or disappearing altogether

3 When the pancreas steps into the physiological action, the cells in which the homogeneous zone has disappeared, or is present only in the shape of an extremely narrow marginal strip, undergo disintegration, while the remaining cells show a diminution of the granular, and an increase of the homogeneous zone

4 At the same time, on the periphery of the alveolus there appear small homogeneous wedge shaped cells, which are gradually lodged between the former elements, and which replace the secretory cells destroyed [They are identical with Podvysotzky's "cuneiform cells," though viewed by Sokoloff in a different light]

5 Simultaneously, there appear round corpuscles in the interstitial tissue of the gland

6 These round cells (leucocytes), probably, serve

as a source from which the homogeneous cells in the alveoli are originated

7 Therefore, the destroyed secretory cells, to all probability, are replaced by new ones, which are developed from leucocytes wandering in the glandular interstitial tissue So far Mr Sokoloff

In a preliminary note in the *Vratch*, No 21, 1883, p 323, Dr Klavdia Ulezko opposes him from the beginning to the end of the matter, pointing to the results of her own investigations conducted in the laboratory, and under the guidance, of Professor M D Lavdovsky Her statements may be given thus

1 No destruction of the secretory cells ever takes place during the physiological action of the pancreas (as well as of the salivary glands, as proved by Professor Lavdovsky in opposition to Professor Heidenhain)

2 Hence, generally, there is no occasion to look about for any substitutes for the pancreatic secretory cells in relation to the regeneration of the latter, this would be the more superfluous, as the secretory cells are capable of proliferation themselves (as was first proved by Gaule)

3 No grounds whatever may be adduced in support of Sokoloff's views concerning the regeneration of the pancreatic cells from leucocytes The active condition of the gland does not stand in any connection with migration of leucocytes The latter—as far as the normal gland is concerned—are present only in too scanty numbers to be taken into any account No transitory forms or links between leucocytes and the secretory cells are (or could possibly be) observed Sokoloff's "homogeneous cells" are, probably, best explained by some defective methods of examination

4 Podvysotzky's "cuneiform cells" have no relation whatever to leucocytes, since they are nothing but artificial products —*London Med Rec*, Jan 15, 1886

Genital Tuberculosis —The interesting subject of genito urinary tuberculosis was dealt with by Dr Simmonds at a meeting of the Medical Society of Hamburg (*Deutsche med Woch*, 1886, No 1) Of sixty cases of tuberculosis of the male generative organs which he had observed, thirty five had been examined after death, and amongst these latter, the epididymis was affected in thirty-one cases, the vesiculæ in twenty-nine, the prostate in twenty six, and the testicle in sixteen—the vesiculæ and prostate being sometimes the starting point of the disease In cases of bilateral tuberculosis of the testicle, it is generally believed that the one organ has been infected by the other through the vas deferens and the prostate, but in two out of five such cases the intra-pelvic organs were entirely free from the disease, which could have been eradicated by a complete castration As to genito urinary tuberculosis, it was stated that the origin of the disease was more frequently in the genital than the urinary tract Of fourteen such cases, the kidneys were involved in only nine, the bladder in thirteen, the vesiculæ in thirteen, the prostate in twelve, and the epididymis in twelve, and clinical evidence was adduced in support of the view that tuberculosis of the urinary bladder is mostly a sequel—even after some years' interval—of tubercular epididymitis Returning to the cases of genital tuberculosis, it was stated that in thirty one out of thirty-five the lungs were more or less involved, but whether primarily or secondarily could not be determined There were three cases of acute miliary tuberculosis apparently due to caseous deposits in the genital organs The majority of the patients were between the ages of 25 and 50, but the list of sixty included two children aged 2 and 7 years respectively, and twelve cases between the ages of 50 and 80 The duration of the disease was most variable, in some cases lasting for years, in others only a few months The clinical features were described, and the differential diagnosis detailed Instances were given of retention of sexual power even in bilateral disease, and in two cases of unilateral disease healthy children were procreated No evidence of transmission of the disease to the wife was found, and Dr Simmonds confirmed the opinion that such transmission did not occur As to etiology, the histories of twenty-six cases showed inherited tendency in thirteen, eleven had suffered from gonorrhœa, four of which were associated with epididymitis, and in four there was a history of traumatism, and it was concluded that traumatism, gonorrhœal or other inflammation, may evoke genital tuberculosis in one who is already the subject of tuberculosis or is hereditarily disposed to it The prognosis in unfavorable, but castration may be performed where there is no evidence of involvement of the pelvic organs, and only slight changes in the lungs —*The Lancet*, Jan 23, 1886

Cobra poison —A paper by Dr R Norris Wolfenden, giving the results of a very thorough and careful chemical examination of the poison of the Indian cobra (*Naja Tripudians*), was read at the Royal Society on December 17 Dr Wolfenden appears to have shown conclusively that the poisonous properties of the venom are due to its albuminous constituents, and that it does not contain any alkaloidal body nor any poisonous acid The toxic properties of the venom are lost when the albuminous bodies are completely removed by processes well known to chemists, or are destroyed by the action of permanganate of potash, which oxidizes the albuminous bodies into oxysulphonic and other allied acids Three kinds of albumen are present in the venom Two of them, globulin, which is in largest quantity, and syntonin, act upon the respiratory centre, while the third, serum albumen, which exist only in very small quantities, probably produces paralysis of the motor centres Whether the poisonous properties of these albumens are due to some peculiarity of their constitution, or whether some hypothetical poison is linked with albumens of ordinary constitution, has not been ascertained, but the possibility of the proteids of the venom being themselves poisonous is rendered more probable by the observations of Schmidt Mulheim and Albertoni, who have shown that ordinary peptone, injected into the blood, may produce poisonous effects, causing a remarkable fall in blood-pressure, and destroying the coagulating power of the blood —*British Medical Journal*, Jan 9, 1886

RE INFUSION OF BLOOD AFTER AMPUTATION

In the *British Medical Journal*, of January 30, MR JOHN DUNCAN, of Edinburgh, has an article on "Re infusion of Blood after Primary and other Amputations" In this paper he gives an account of a case of railway injury, in which the left leg had been crushed, amputation being required at the lower third of the thigh The man had lost a large amount of blood on account of a tourniquet not being screwed up tight enough Eight hours after the injury the patient was pallid and collapsed, with a quick, irregular, and fluttering pulse, when it was perceptible Alcohol, injection of ether, and elevation of the limbs had scarcely any effect, and it seemed impossible that he could survive an amputation There seemed to be some hope in intravenous injection, however, and it occurred to Mr Duncan that the blood lost during the operation might be utilised

The patient was anæsthetized with chloroform, followed by ether (a method which, if the reader will pardon the digression, certainly has very great advantages in many cases) The limb was rapidly removed, and the blood which fell from it (about three ounces) was caught in a dish containing a solution of phosphate of soda "After the arteries had been tied, it was difficult to say for a time whether the patient was dead or alive, but I proceeded to inject the blood and phosphate of soda, mingled with distilled water in the last syringeful to increase the quantity In all, about eight ounces were thrown into the femoral vein on the face of the stump The quantities are not exact, because the graduated dish was necessarily flat to catch the blood, but are correct within a drachm, or at most two" The patient was put to bed, in front of a fire, and teaspoonfuls of weak brandy and water were given frequently By the time that he was in bed the pulse had become very perceptible, steadily improved during the night, and the man recovered

It is apparent that the dominant idea in this procedure is to save and utilise the blood, which would otherwise be lost, flowing from the amputated limb The loss or saving of a few ounces of blood in a case of collapse may make all the difference of death or life "No doubt," says Mr Duncan, "a simple saline fluid may for a time supply the means of working to the empty heart and vessels, but, in my experience, the benefit is only temporary—for one reason, because it is essential that the blood forming organs should act, and they require suitable nourishment, like every other part of the frame" We know how difficult it is to empty shattered limbs of blood, and a small or large quantity may always be caught at the time of incision and when the arteries are tied Mr Duncan has now carried out his method in a sufficient number of cases to permit him to speak with confidence as to its safety and value The idea occured to him, he says, from a considerable experience in transfusing blood from one person to another, and seeing how imperfect and sometimes dangerous are the ordinary methods of transfusion Mr Duncan relates an interesting case in which his house-surgeon, Dr Carmichael had himself bled to six ounces, and used the blood, mixed with the phosphate of soda solution, in a case of intra pleural hæmorrhage after resection of a rib for empyema The patient, though apparently moribund, rallied quickly and recovered

The solution of phosphate of soda used in one case was of 5 per cent, and one part of this was added to three parts of blood, but our author thinks that a slightly larger proportion is advisable, and has increased it in amputation cases In one case the soda solution was unintentionally made of double strength, and the mixture remaining after re infusion was not coagulated at the end of half an hour (The soda solution, it need scarcely be said, is used to prevent coagulation of the blood) For the introduction into the vein of the receiver Mr Duncan uses a short glass tube, of the size of a No 6 catheter, having a pen-shaped point "To its outer end, made slightly bulbous, about two inches of India-rubber tubing is attached A simple glass syringe, holding four ounces, whose nozzle fits the tubing, is perfectly effective" The temperature is kept up by surrounding it (the tube or syringe?) with boric lint, wrung out of hot water The phosphate of soda solution is kept in a graduated glass vessel floating in warm water, and into this the blood is received. The glass is purified by prolonged immersion in a solution of bichloride of mercury, and washed with aseptic water after removal from the antiseptic solution, and before being used.

When the operation is performed after an amputation, "the most convenient vein is selected on the face of the stump, the glass point is inserted, and a catgut ligature put round it. (The ligature is used to hold the glass point in the vein, and prevent escape of blood.) While the process of ligaturing the arteries is going on, the blood is caught by one assistant, who adds the soda solution as required, and is slowly injected by another. There is no time wasted, and the amount put into the circulation is precisely proportioned to what the patient would otherwise have lost, *plus* what amount of saline solution the surgeon may think right and appropriate to the case." This process of reinjecting the patient's own blood, very probably says Mr. Duncan, is incompatible with the use of spray or irrigation during the operation.

The method of preventing coagulation by phosphate of soda, and injection by means of the apparatus described, has been used by Mr. Duncan in several cases of pernicious anæmia. While we may justly object to applying the term re-infusion in such cases, the blood being obtained from another person, we must recommend the method for these cases in preference to the ordinary methods of transfusion of blood. In such cases a vein in the arm of the patient is exposed, and under it a double thread of catgut is passed. Blood is then drawn from the donor into the dish containing the phosphate of soda, and the two are gently mixed by means of a glass rod. An assistant fills the syringe while the operator opens the exposed vein of the patient, the lower thread of catgut being gently pulled upon to prevent hæmorrhage. The tube is now inserted, the upper thread tied around it with one knot, the lower one being secured and cut off short. The blood is then slowly injected, "the India-rubber tubing being pinched when the syringe required to be refilled." The upper piece of catgut is tied and cut short when the operation is finished and the wound is stitched up.

In cases of anæmia care must be taken to finish the injection before the blood coagulates, as the soda solution will only prevent coagulation for a certain length of time, and, on the other hand, the injection may be made too rapidly for the patient. Obviously neither of these errors can be well committed in employing the method after an amputation. Inasmuch as Mr. Duncan unintentionally doubled the proportion of soda solution in one case, and found that the blood remained fluid for half an hour after being mixed with the soda, there seems to be no objection to making the proportion of soda solution greater than one part to three. Could not this method be employed in cases of post partum hæmorrhage? While there are certain objections that may be raised to re-injecting the blood which has been lost in these cases, there is certainly no reason why the blood should not be obtained from another person. Of course the amount of blood lost in severe cases of post partum hæmorrhage is so large that the patient might die before the mixture could be properly made unless every preparation had been made. Still, this method may be carried out as quickly as some of the procedures that are recommended and used in these cases. Certainly for the treatment of collapse after post partum hæmorrhage it must be regarded as more safe than the intra-venous injection of milk, and very much more quickly performed. There is also a question whether it is not more to be recommended in cholera collapse than the intra-venous injection of salt solutions, which has been so much discussed in the foreign journals during the past two years.

THE RELATION OF CHOREA MINOR TO ACUTE ARTICULAR RHEUMATISM AND ENDOCARDITIS.

The latest contribution to this vexed question is in the *Berliner Klinische Wochenschrift*, No. 2, 1886, from the pen of DR. E. PRIOR, Privat Docent at Bonn. He gives the result of the painstaking investigation of 92 cases of chorea minor with special reference to its connection with endocarditis and acute articular rheumatism. In 87 out of the 92 cases the chorea was not complicated by any disease of the heart, nor could there be discovered the slightest trace or history of previous attacks of rheumatism. In one case, that of a girl 10 years of age, the patient was said to have had some affection of the heart several months before, but reliable facts concerning it could not be obtained. On the other hand, there was unmistakable evidence of an attack of rheumatic arthritis in the fingers of the right hand two weeks prior to the outbreak of the choreic manifestations.

Since experience teaches that evidence of endocarditis may be discovered *post mortem*, even when the most thorough physical examination *intra vitam* has failed to detect its existence, Prior thinks this case may be not unreasonably classified among those in which there is a combination of the three diseases in question. In four other cases there was valvular disease of long standing In three of them mitral insufficiency had been diagnosticated years previously, but there could not be ascertained any history of rheumatism The fourth patient, a girl of 19, had suffered with inflammation and swelling of the knee-joint several years before Although a definite connection between the valvular lesion and the chorea ought not to be asserted in these cases without further proof, Prior yet inclines to the opinion that the heart disease may have borne some etiological relation to the St Vitus's dance It is not impossible that a fresh endocarditis may have been lighted up at the time of the commencement of the chorea It appears, therefore, that in but 5 out of 92 cases, that is 5 4 per cent, can there be any suspicion of a connection between the chorea and endocarditis and rheumatism, while in 94 6 per cent of the total number, the chorea was absolutely free from these complications

There are other facts, also, which agree with his statistics, in Prior's opinion, in their opposition to Rogers's theory, that chorea and rheumatism are different expressions of one and the same pathological law It is notorious that St Vitus's dance is a disease of childhood by preference, whereas rheumatism, as a rule, attacks adults between the ages of 20 and 35 years Moreover, chorea occurs most frequently among girls, while rheumatism and endocarditis resulting from rheumatism are most frequently observed in males Furthermore, in those cases of chorea in which the disorder seems to have its origin in imitation of choreic companions, and "epidemic-like, invades whole schools," it certainly would be absurd to claim that all of its victims have been subjects of rheumatism or rheumatic endocarditis

On the whole, therefore, Prior inclines to the opinion that any etiological relation existing between these diseases and chorea, in so constant and definite a manner as to form a law, does not exist There cannot be in choreic individuals some diathesis, as suggested by Begbie, Watson, Branson and others, which finds expression sometimes in rheumatism, at other times in St Vitus's dance It is not unlikely, he thinks, that in some instances the disease may result from reflex irritation of the cardiac distribution of the phrenic nerve, as by a greatly enlarged heart This is in accord with the theory promulgated by Bright In other cases Prior believes it not improbable that emboli may occasion choreic manifestations, as maintained by Kirkes, Tuckwell and others He does not, however, support Broadbent's explanation which would attribute the occurrence of chorea to capillary embolism in the immediate vicinity of the corpora striata

Dr Prior's paper cannot be said to contribute any facts particularly new or original It is in accordance with the position pretty generally taken by his countrymen, which is conservative Germain Sée and Roger are ardent defenders of the rheumatic origin of chorea, or rather, of the identity of the two diseases Their figures show a strikingly large proportion of choreic cases complicated with rheumatism, and Roger goes so far as to declare that in every instance of St Vitus's dance it has been preceded, accompanied or followed by rheumatic symptoms There is considerable lack of uniformity on the part of German observers as regards the etiology of the disorder, but on the whole they are opposed to all the conclusions of their French neighbors Of 252 choreic patients observed by Steiner, of Prague, only 4 gave a history of rheumatism The English are also somewhat divided, but on the whole occupy very much the same ground as the French The contradictoriness of statistics concerning the relation between the two diseases is curious In 1846 Hughes published a report of 108 cases, of which but 14 gave evidence of rheumatism together with the chorea In 1856 he published 209 other cases, 104 of which were carefully examined In all but 15 of these either rheumatism or rheumatic endocarditis existed It is probable that the French and English observers have been somewhat misled in their conclusions by the great frequency with which rheumatism occurs in their climates Diversity of opinion likewise exists in this country Jacobi is reported to agree with Roger, while J Lewis Smith states that probably the majority of American observers incline to the conservative judgment of the Germans

The subject is an interesting and highly important one Notwithstanding the investigation it has received, it does not appear to be any nearer solution now than years ago There is ample opportunity for the clinical study of the disease, but it so seldom proves fatal, that the opportunity for a *post mortem* investigation of its morbid anatomy is limited Hence we fear the etiology of chorea minor will continue for years to come to be as great a riddle as at present

---

EDUCATION FOR THE WORK OF LIFE—"THE MAIN QUESTION IS, WHAT SHALL A BOY STUDY UNTIL HE IS CAPABLE OF DETERMINING WHAT PROFESSION TO CHOOSE?"

This question forms the closing sentence of a familiar letter from a valued correspondent who had been advocating a thorough and protracted study of Greek and Latin, or the so called *classical* course, as the most essential preparation for eminence in medicine or any other profession The question plainly implies that neither the boy nor his parents or guardians can properly determine what profession or calling in life will be best suited to his tastes and mental qualities, until he has attained an age sufficient to give a degree of maturity of judgment, but in the meantime the boy's education must be progressing, and we are asked, what shall he study?

We answer, *first*, that every boy should study thoroughly, persistently and accurately the elementary branches that constitute the foundation of all education By the time he has become well trained in the correct use of his own native language (the English) in reading, writing and speaking it with ease and accuracy, and has acquired a reliable knowledge of the more elementary mathematics, geography, and history, his mental faculties will have become sufficiently developed to enable an intelligent parent or competent teacher to discern clearly the important natural mental aptitudes and inclinations that characterize the boy And on a fair appreciation of these must be founded, not a choice of a profession or calling for life, but the further direction of his education, in the most profitable manner, until he reaches the age and knowledge of the professions and occupations of life to enable him to make his own choice

Perhaps the most important era in the educational history of every boy is the one we have just indicated as completing a knowledge of the fundamental branches of all education If his real mental aptitudes are correctly appreciated, and he is permitted to enter upon such further studies as are congenial to him, whether they be in the direction of the physical and natural sciences, in the field of literature, history and art, or in the acquisition of ancient and modern languages, he will make good progress and will acquire real mental discipline, development, and useful knowledge for the work of after life To ask us to name some one definite course of study for all our boys, or even for all who are expected to choose some one of the professions, would be very like asking us to select one pattern and size of shoes to fit all the boys alike Almost all our best universities, colleges and higher schools provide not only the full *classical* course, but the "Latin scientific," and scientific courses, thereby affording a proper selection fitted for the different mental tastes and aptitudes of different scholars—and that boy will attain the highest eminence in whatever pursuit of life he chooses, who is guided at the proper age into that course of studies which is most congenial to his natural mental qualities To insist that a boy shall be drilled for seven or eight years in Greek and Latin when every lesson is about as repugnant to him as an old fashioned dose of an infusion of senna and salts, is an admirable method for making him an adept in the art of "shirking" and nothing else

It may possibly be thought by some that, in discussing this subject of early education, we are treading upon extra-medical ground But when it is remembered that the physician must deal with both bodily and mental ailments, and that one of his highest duties and most proper studies is the prevention of disease, and showing how it may be prevented, it will be evident that the discussion of the faults of education is certainly within the true professional field Physicians, and intelligent people generally, know that physical constitutions are different, and it seems strange that, in spite of the cumulative evidence of centuries, it is so seldom that people—and "educators" especially — recognize the fact that mental aptitudes, tastes and powers are as different, or more so, than physical constitutions It will be a bright day for humanity when parents and teachers open their eyes to the fact that boys are not pegs of the same shape and size, all to be stuck into the same hole No two trees are alike, and no two leaves on the same tree, and common observation shows that even the lower animals, of the same kind, differ in traits, instincts and mental capacity Who has ever seen two brothers, even twins, alike in mental capacity and aptitude?

ALFRED C POST, M D , LL D

In the death of DR ALFRED C POST, M D , LL D , which occurred at his home in New York, of cystitis, on Febuary 7, America has lost one of her most scholarly and distinguished surgeons, and one who, though he leaves no huge volume as a monument and evidence of his work and learning, will long be remembered for his marked dexterity and precision in operating, and his great mechanical ingenuity in devising new operations, new instruments and new appliances With these qualities added to an encyclopædic knowledge of the literature of his profession, and a rare goodness of heart and love for his fellowmen, it is not remarkable that he should have attained such eminence in his profession, or that he continued his work almost to the day of his death, having been in the active practice of medicine for almost fifty six years As is well known his work of late years has been mostly in the field of plastic surgery, and his contributions to this subject have been very many and very important

SOCIETY PROCEEDINGS

CHICAGO GYNÆCOLOGICAL SOCIETY

Regular Meeting, December 18, 1885

THE PRESIDENT, DANIEL T NELSON, M D,
IN THE CHAIR

W W JAGGARD, M D, EDITOR

DR W W JAGGARD read a paper entitled

TWO RECENT MODELS OF THE AXIS TRACTION FORCEPS

The object of the paper was not the description of some modification by the writer, although such a contribution to the literature of the subject would be perfectly legitimate in view of Pajot's witty remark to the effect "that he does not reproach a man for having invented a forceps, since that might happen to any one"—(*Barnes*)

Breus and Felsenreich, formerly assistants respectively in the third and first obstetrical clinics of the Vienna General Hospital, have recently made important alterations of Tarnier's axis traction forceps The importance of these modifications was so great that no apology was demanded for calling attention to the instruments

As the result of the labors of Sir J Y Simpson, Nageli, Busch, Levret and others, the low forceps operation may be regarded as a comparatively perfect operative procedure, both as regards instruments and modes of operation The case is different with the high forceps operation This operation is always difficult, and sometimes dangerous, with the instruments mentioned The cause is obvious The applied force can be resolved into two components, one in the direction of the axis of the plane of the inlet, the other perpendicular to the first, directed towards the posterior surface of the symphysis The first component is alone active in causing the descent of the head, the second makes the extraction more difficult, and exposes the maternal tissues between the head and symphysis to traumatism As remarked by Schauta (*Grundriss der Operativen Geburtshilfe*, Wien, 1885, p 162), "the unphysiological, and therefore mischievous element in the operation of the forceps, as compared with the effects of uterine contractions, when the head is at the inlet, consists in the fact that the forceps draws the firmly held head in a direction which it can never follow, while the uterine contractions simply drive the head into the pelvic cavity, and permit it after that to seek the direction of least resistance" The older obstetricians, fully recognizing these facts, attempted to apply the power to the classical forceps in such a way as to secure a more favorable direction of traction Osiander (1799) and Stein, Sr (1805) may be mentioned among the older obstetricians who devised instrument for making traction in the axis of the inlet Hermann (1844) (Kilian's *Armamentarium lucinæ novum*), constructed an instrument in which an iron lever is attached to the lock J P Hubert (1860) attached a vertical iron lever to the extremities of the ordinary forceps This lever was subsequently attached to the lock Eugène Hubert, his son, constructed an axis traction forceps with parallel branches and a sharp perineal curve Chassagny, Joulin, Pros, Poulet, Moralès Apaca (1871) and others, have constructed various types of axis traction forceps at a more recent period In many of the modern French instruments an attempt has been made to apply some of the well known principles of veterinary surgery

In 1877, Tarnier, following in the wake of Hermann, Hubert, and the more recent French investigators, constructed and published a description of his well known instrument Since that time, he has produced more than thirty distinct models His last model consists of the classical forceps of Levret (without a perineal curve), and axis traction rods attached to the posterior, inferior border of the blades, or spoons Tarnier claims a number of advantages for his instrument over any other axis traction forceps He claims that it is superior to the classical instruments in the following particulars

1 It is possible to apply traction in the direction of the principal pelvic axis

2 Sufficient mobility is conferred upon the child's head to permit it to seek its way through the pelvis in the direction of the least resistance

3 The handles indicate to the operator the direction in which traction should be made

With reference to the first proposition, it may be said that traction with Tarnier's forceps is not made in a curved line, accurately coincident with the principal pelvic axis, when the head is at the inlet Nor is traction in this direction absolutely necessary, as remarked by Schauta, seeing that the resultant of the forces, developed by uterine contractions, and the resistance opposed by the pelvic floor, does not propel the head in the direction of the principal pelvic axis

The handles, as indicators of the direction in which traction should be made, are of relatively slight value

On the one hand, the operator who is at all qualified to apply the forceps to the head at the inlet, ought to have a correct conception of the direction in which traction should be made On the other hand, strict attention to the handles may prevent the operator from observing a number of important events, ex gr, the relation of the head to the vulva, slipping of the instrument, etc (Schauta)

Finally, the handles are not a correct indicator of the direction of the principal pelvic axis

The advantage of Tarnier's forceps over its predecessor's lies in the mobility conferred upon the fœtal head by the joint, uniting the blades and the so called axis traction rods The head does not follow the direction of the principal pelvic axis, but seeks the path of least resistance In consequence, the operator is spared the fatigue of unnecessary effort, and the mother, the dangers of traumatism from violent traction

I Breus has recently constructed an instrument which has a great advantage over the forceps of Tarnier, in that a greater degree of mobility, during traction, is conferred upon the head The continuity of the blades (Loffel) is interrupted at, and below, the fenestræ, by a strong flat joint, which admits of movements in the sagittal direction, and corresponding variability in the angle at which traction is applied to the head. The superior ribs of the instrument are prolonged, and turned upward like spurs. These spur like prolongations are joined by a metallic rod in order to preserve a certain parallelism of the blades. Apart from these peculiarities the instrument is identical with the original model of Sir James Y. Simpson's forceps.

This instrument, devised by an obstetrician of large experience, is employed on an extensive scale at Vienna, in Gustav Braun's obstetrical clinic. Schauta (*Grundriss der Operativen Geburtshulfe*, Wien, 1885, p. 164, et seq.) recommends the instrument as the most perfect axis traction forceps in existence, to his classes at the University of Innsbruck. Furst's recent favorable note on Breus's forceps in the *Centralblatt fur Gynakologie*, 1885, is well known.

II. *Felsenreich's Modification of Dr. Alexander Simpson's Modification of Tarnier's Axis-Traction Forceps.*—In 1880, Dr. Alexander Simpson, of Edinburgh, sent to Dr. Carl Braun a modification of Tarnier's axis traction forceps, which at once superseded the French instrument in the first obstetrical clinic of the Vienna General Hospital. Simpson substituted Sir J. Y. Simpson's original model of the classical instrument for Levret's. The compression screw is located on the upper third of the superior surface of the handles. Comparatively unimportant modifications were made with reference to the traction-rods, and the hard-rubber handle, into which the traction-rod fits. Felsenreich has materially enhanced the value of Dr. Alexander Simpson's instrument by a number of important alterations.

Felsenreich's modification of Dr. Alexander Simpson's axis traction forceps, as shown by the model presented, manufactured by Mr. J. Leiter, of Vienna, during October, 1885, consists of the following parts:

1. A practically unaltered model of Sir James Y. Simpson's forceps (*Wiener Schulzange*).
2. Button-hole perforations, one behind each fenestra, into which traction-rods are inserted, and maintained by the buttons on the ends of the rods.
3. A removable compression thumb screw, which sinks into a groove made in the extremities of the handles of the Simpson forceps.
4. A hard-rubber handle for the traction rods. The arrangement for the insertion of the traction rods into the hard-rubber handles differs from the mechanisms in Tarnier's and Alexander Simpson's axis traction forceps.

The attachment of the compression screw to the ends of the handles, and certain changes in the curve of the axis traction rods, have been made at a comparatively recent period, but prior to 1883.

Dr. L. E. Neale, of Baltimore, published an article in the September number of the *American Journal of Obstetrics*, 1885, entitled "An Obstetric Forceps." In this paper Dr. Neale describes an axis-traction forceps, devised by himself, which differs in no essential particular from Felsenreich's modification of Alexander Simpson's instrument. Editorials have appeared in The Journal of the American Medical Association, September 26, 1885, and the *Therapeutic Gazette*, December 15, 1885, calling attention to the facts, that a forceps, identical with the instrument devised by Dr. Neale in all essential details, had been constructed several years before in Vienna by Dr. Felsenreich, and that Dr. Neale had probably forgotten the existence of that instrument, although he had seen it in active operation in the lying in ward of Carl Braun, in various courses on operative obstetrics, and in the shop of Mr. J. Leiter, the instrument maker to the Vienna General Hospital. The only criticism that the writer would make, with reference to these editorial notes, was, that Dr. Felsenreich, not Dr. Neale, applied the compression thumb screw to the ends of the handles. Dr. Neale has made some trivial modifications in the hard rubber handles and the mode of insertion of the traction rods. Dr. Neale made no allusion to Alexander Simpson's modification of Tarnier's instrument in the paper mentioned, and his allusion to Dr. Felsenreich's suggestion of the button hole joint is, to put the case very mildly, disingenuous.

In conclusion, Dr. Jaggard said that he was of the opinion that the axis-traction forceps of Breus and Felsenreich were superior to the most recent model of Tarnier's, or any other axis-traction forceps that had come under his observation. He requested that the discussion be limited to the comparative merits of the forceps presented—Breus's and Felsenreich's—and other recent models of the axis traction instrument.

Dr. John Bartlett said that he had devised an axis traction forceps in 1880, identical in principle with the instrument constructed in 1860 by the elder Hubert. His attention had been first called to the coincidence by Professor Lahs's monograph on *Die Achsenzug Zangen*, Stuttgart, 1881.

Dr. Henry T. Byford thought the instrument described by Dr. Neale in the September number of the *American Journal of Obstetrics*, 1885, was identical in all essential particulars with Felsenreich's modification of Alexander Simpson's instrument devised two or three years before.

Drs. Philip Adolphus, A. Reeves Jackson, H. P. Merriman and H. P. Newman had never observed indications for axis traction forceps, had never employed such instruments, and thought they were unnecessary.

Dr. Jaggard said he had no desire or intention to discuss the general subject of axis traction forceps, and had expressly requested that the discussion should be limited to the consideration of the relative merits of the instruments presented for examination, (Breus' and Felsenreich's) and other modifications of the axis traction forceps. He thought that gentlemen of limited experience in cases indicating the high forceps operation, and particularly those who had absolutely no experience with axis traction instruments, should be temperate in their criticism. Carl Braun, Pajot, Charpentier and others had practically rejected such instruments, but only after serious and experimental consideration of their merits. On the other hand, many younger obstetricians, including Schauta, Felsenreich, Breus, Ehrendorfer, thought there were cases in which they might be profitably employed.

Dr. Henry T. Byford then read a report of a case of

PELVIC ABSCESS, WITH REMARKS UPON THE TREATMENT.

Mrs. T., aged 25 years, married five years, German descent, of nervous temperament, small and slight in figure, but in good general health, consulted me, during the fall of the year 1884, for sterility and dysmenorrhœa. She had never menstruated without pain, but had otherwise enjoyed good health. An examination revealed a small uterus and cervix, with acute anteflexion and consequent apposition of the anterior and posterior uterine walls. Slippery elm tents, used about once in eight days, alternated with glycerine tampons, had for their effect a gradual relief of the dysmenorrhœa.

About the middle of the following February, I was called to her house to treat her for a severe attack of pelvic cellulitis, contracted a week before while returning home from a dance. The whole pelvic connective tissue seemed to be involved, and several large tender lumps could be felt externally in the left iliac region.

Six weeks from the beginning of the attack, an abscess opened into the anterior wall of the rectum, about two inches from the external anal orifice. On account of the extreme debility of the patient, her horror of operative procedures, and the absence of any well marked fluctuation, all surgical interference with the suppurative process had been out of the question. Palliative treatment was instituted and continued without effect until the 6th of June. In the meantime the pulse remained in the neighborhood of 120° F., and the temperature fluctuated between 99° F. and 102° F.; attacks of acute suffering and septicæmic diarrhœa required opiates for their relief, the bacillus tuberculosis was discovered in the pus, yellow pigmentary deposits covered her face, and emaciation became extreme, her weight ranging between eighty two and eighty three and one-half pounds. Her courage began to fail, and finally after the concurrent recommendation of the consultants, Drs. Wm. H. Byford, J. E. Owens, George M. Chamberlin and Martin Matter, she consented to an operation. Accordingly, on the 6th of June, Dr. Wm. H. Byford operated according to his usual method in such cases. After etherization, he forcibly dilated the sphincter of the anus, tore open the fistulous track with the finger, and then enlarged the abscess in the same manner, in the direction of the lowest part of the cavity, until it readily admitted two fingers. He then made a digital examination, and found the abscess to extend across the pelvis, behind the uterus and broad ligaments, above the level of the fundus uteri on the left side, and to be filled with bands and projecting masses of granulation-tissue of about the consistency of freshly coagulated blood. Previous treatment, except to diminish and control the septicæmia, had evidently been a complete failure. All of this medullary tissue was then scooped out with the finger and the cavity thoroughly cleansed with a two and a half per cent. solution of carbolic acid.

The higest temperature after the operation was 99° F., on the day following. Perfect drainage had been secured, for at the time of each dressing no pus was found inside of the abscess. The cavity of the abscess was treated by irrigation with antiseptic solutions, insufflation with iodoform and the introduction of cupric sulphate.

Early in September she was attacked with the then prevalent epidemic, dysentery, and died on the 23d instant. At the post-mortem examination, made about thirty hours after death, I was somewhat hampered on account of a promise, exacted by the husband, that no organ should be taken out of the body, and by the fact that I had but thirty minutes for work before train time. The body had again become extremely emaciated. Abdomen was flat. An incision was made from a little above the umbilicus to the pubic bone. The pelvis was filled posteriorly with a solid mass of plastic tissue, which had drawn the uterus backwards to within about half an inch of the sacrum, so as to put the anterior vaginal wall upon the stretch, and had buried the uterus and other pelvic organs in its substance. Both round ligaments were seen issuing from this mass. It was necessary to cut down about half an inch before reaching the depressed uterus, and to tear through solid tissue behind it to arrive at the rectum below. The finger broke through into the rectum, behind the dimpled cicatrix that marked the site of the former outlet of the abscess. The left broad ligament was then found to be represented by, or inclosed in, a tough band half an inch thick antero posteriorly, extending from the uterus to the left side of the pelvis. The left ovary could not be found. A small flat piece of what seemed to be ovarian tissue was found adherent to the bladder on the right side. The right broad ligament was apparently disorganized and inseparable from the plastic deposit. The rectum was held inflated at the point where it issued from the pelvis, was dark-colored and injected on its external surface, and blackish and softened on the internal. Neither the appearance nor the odor of an abscess could anywhere be discovered.

There seem to have been two hinges, as it were, upon which the treatment of this abscess turned: first, the operation per rectum, second the cauterization by sulphate of copper. Both secured a large opening at the lowest portion of the pyogenic cavity, and brought away the unhealthy granulation tissue. Had the patient consented to have the unobstructed outflow of the pus maintained by one or two subsequent dilatations, similar to the first one, the cure would undoubtedly have been more rapid. As it was, the contracting sphincter and abscess outlet rendered the drainage and irrigation imperfect. Progress toward recovery was, however, again inaugurated upon the melting away by the sulphate of copper of the newly and imperfectly formed cicatricial tissue, reproducing the opening made at the time of the operation and by the destruction of the degenerative deposits and cauterization of the chronic pyogenic surface. The only kind of treatment preferable to this free drainage and clearing out method is the strictly antiseptic, which, after the pus has once found a way into the rectum, can only be accomplished by first closing this septic inlet The treatment by a counter-opening in the vagina is much less preferable, because a recto-vaginal fistula, difficult of cure, and liable, like anal fistula, to inoculate the system with tuberculosis, would be left

The treatment by abdominal incision cannot for a moment be entertained, for at least two reasons

1 It is necessarily followed by a recto abdominal fistula of great length, which is incapable of being promptly cured, and is apt to become an unfailing source of systemic infection Those patients already operated upon, as far as reported, have usually either died shortly, or within a year or two, imperfectly cured They would have, on an average, lived about as long without the operation In fact, it is not impossible that one such, whom I had, previous to the operation, an opportunity of watching for a short time, would finally have recovered through the process of nature To operate as does Lawson Tait, before the abscess has discharged, and then treat it antiseptically through its single opening, is an entirely different matter

2 The danger of an abdominal incision should never be incurred without a prospect of compensation in the way of bettering the patient's chances of recovery Neither theory nor practice as yet prove such compensation to be attainable

In some cases one dilatation per rectum, without after-treatment, has sufficed for a cure, in other cases two or more, with subsequent antiseptic irrigations, have become necessary But as a general rule it may be said that, unless instituted too late, the procedure is safe and the recovery sure

DR CHRISTIAN FENGER said that when a peri-uterine abscess points somewhere in the vagina around the lower part of the uterus, no surgeon would, of course, think of doing anything but opening the abscess, inserting a drainage tube, and by washing out, endeavoring to effect the closure of the cavity But in some cases the opening into the vagina is just as ineffective as a spontaneous opening into the rectum In obstinate cases of this kind, laparotomy, at a later period, will have to be performed There is, however, no doubt that secondary invasion of septic poison, when the abscess is opened from the vagina, is much more difficult to prevent than invasion into the abscess from the abdominal opening It is only in this way that we can account for the difference in the course of the after treatment of peri-uterine abscesses opened through the vagina and through the abdominal cavity, a difference that Lawson Tait rightly calls attention to as being decidedly in favor of the abdominal operation Here the abscess closes more quickly, and the course of the after-treatment is much less febrile than in the vaginal operation

Sometimes a peri uterine abscess will point into the rectum, sufficiently low down to permit of an opening here It does not seem probable that the access from the rectum will be very promising, as effective drainage is next to impossible, but the cases of cure by spontaneous opening into the rectum evidently make an operation here permissible, and perhaps advisable, but only as a trial If the abscess does not retract within a reasonable time, other measures must be resorted to

It is needless to state that if a parametritic abscess points anywhere along the iliac fossa, it should be opened and drained from this point, but this does not belong to the subject of to night, as he desired to call attention only to strictly circum uterine abscesses, which can only be reached from the vagina or from the supra pubic region

When a circum uterine abscess does not point downward, and, in fact, does not point anywhere, it is then the surgeon's task to find the safest way into the abscess through a smaller or larger amount of surrounding tissues He first considered the vaginal operation When so eminent an authority as Schroder, of Berlin, advocates this method of reaching a high peri-uterine abscess there must be cases in which this operation is advisable From a general point of view an extra peritoneal outlet of the abscess through the vagina would seem to be safer than laparotomy, upon the same grounds as a vaginal hysterectomy is safer than Freund's abdominal hysterectomy, and Schroder's successful operation, already mentioned, vouches for the method

At the same time Dr Fenger firmly agreed with Lawson Tait, that there are some grave objections to the vaginal operation In the first place, a high seated peri uterine abscess is difficult to reach It is difficult to work with safety two or three inches above the introitus of the vagina, in tissues that are immovable, and where the parts cannot be drawn down toward the operator, These difficulties are, of course, of less importance in the hands of an operator like Schroder, but increase in significance for less experienced surgeons But the operation through the vagina is more or less an operation in the dark We may be dissecting up along the posterior surface of the neck of the uterus, and may open into recesses of the peritoneal cavity between the abscess and the uterus Further, it might be easy in this place to open into the rectum Another danger, especially in abscesses between the two layers of the lateral ligament, might easily arise from the rupture of the large uterine vessels running in the wall of the sac It would be exceedingly difficult, and he should say next to impossible, under such circumstances, to secure and ligate these vessels, the point of ligation being so high up, the working space so small, and the tissues so immovable

All these objections and dangers we do not encounter in laparotomy We can see distinctly, and recognize with our own eyes, every particle of tissue we have to divide, the large uterine vessels, if divided, can easily be taken up and ligated There is no risk of having any communication between the abscess and the peritoneal cavity, which we cannot either close up or drain If the laparotomy last longer, and gives more technical work to the surgeon, it seemed to him that these objections are fully balanced by the advantage of not being obliged to work in the dark, of not having to battle with enemies that we cannot see, and consequently cannot guard against

But these are not the only advantages of laparotomy, as compared with the vaginal operation The free access to the whole interior of the abscess cavity has also to be taken into account By laparotomy, the abscess is laid open to about the same extent as a tubercular peri articular abscess We can examine the whole interior of such a cavity, and scrape off, or remove by other means, whatever objectionable material we may find, cheesy matter, tuberculous tissue, fungoid granulations—since we can see clearly every place where the instrument is applied, without any danger of going through the abscess wall into any surrounding cavity or organ It is more than possible that this free access to the abscess wall has something to do with the speedy recovery subsequent to laparotomy, as compared with the vaginal operation[1] But, of course, there will always be connected with laparotomy the inherited dread of opening that ominous peritoneal cavity Modern surgery, however, is making steady progress in diminishing these dangers Thus, the dread, as well as the safety of the patient will, to a great extent, rest in or depend upon the care and skill of the operator

Dr W H Byford did not wish to comment upon the contents of the paper, further than to express himself in reference to the mode of operating adopted in consultation with the gentlemen mentioned A large number of pelvic abscesses can be managed through the rectum with more facility and safety than any other medium of approach to the deep seated portions of the pelvic cavity He did not know whether there are any cases situated wholly in the pelvic cavity but that can be reached, opened and evacuated through the rectum It may not always be the most eligible direction to approach collections of pus In instances in which the pus is making its way toward the vagina, and fluctuation can be felt through the vaginal walls, it ought to be evacuated through that canal, but when the point of discharge is not thus indicated, the exploration is most easily made through the rectum, and all chronic cases that have already commenced to discharge into the rectum can and ought to be treated from the cavity of that viscus He would make no exception, however high the opening might be, so it was within the pelvic cavity By proper preparation the whole length of the rectum can be reached, from the sphincter to the promontory of the sacrum and from any part of it the pus evacuated, the pyogenic cavity explored and drainage and irrigation safely and securely accomplished He believes the dangers of this mode of operating to be incomparably less than by abdominal section, and the other results of the operation—such as drainage and disinfection—more complete

To effect the objects mentioned, the sphincter should be stretched to laceration, and until there is no tendency to immediate contractions of the anal opening, and till it can be dilated to the full extent of the rectal cavity Thus thoroughly opened, the whole extent of the rectum can be explored with great facility, and often by means of dilators can be seen, and instruments used under the eye of the operator If the pus is to be sought after, palpation with the fingers becomes easy and satisfactory, if it is being evacuated, the orifice seen or felt and such treatment as is desired applied He very much prefers stretching and tearing for the purpose of increasing the size of the orifice to the use of cutting instruments The opening will not so readily close, and there will not be so much hæmorrhage In effecting the discharge of the pus, we should remember that the reason why the pyogenic cavity is at no time wholly obliterated is because there are irregular loculi or pockets so situated that they do not empty themselves The opening should therefore be made large, the parts torn by the fingers until this inferior margin of the opening is as far below the main body of the cavity as practicable With the fingers the interior bands and partitions should be completely broken down, and the interior of the cavity rendered as nearly symmetrical as possible This will enable the whole of the contents of the cavity to escape by means of gravity, and the fluids used in irrigation find their way out without difficulty In addition to the shaping of the cavity, the large granulations—generally so abundant—should be scraped away by the fingers or by a dull curette, thus freshening up the lining membrane of the pyogenic cavity, and converting it from a state of indolent ulceration to one disposed to heal This process of curetting also produces a change in the capillary circulation that makes nutritive processes more salutary Often in very indolent cases the sphincter will recover contractile power to such a degree as to require one or more repetitions of the operation The same thing may be said of the margin of the orifice in the intestine We will be obliged to enlarge it and treat the cavity as before

In the case narrated in the paper, the action of the sulphate of copper seemed most useful, and contributed the last influence necessary to the cure He has said nothing about the more common items of treatment, such as irrigation, disinfection and stimulation His intention is to show the facility with which, in many instances, these purulent collections can be reached and treated by dilating and distending the rectum, and the comparative safety of such proceedings

Dr E C Dudley said that the experience of Dr Byford and others in the treatment of pelvic abscess by this operation must be considered as proving the great value of the operation in cases in which the abscess can be easily approached and thoroughly drained by dilatation of a sinus between the abscess-cavity and the rectum It would, however, appear on general principles, that sufficiently free and long continued drainage would in many cases be almost unattainable, and that an abscess cavity left thus to heal must often be the starting-point of sinuses formed by the uncontrolled burrowing of pus in many directions The almost inevitable invasion of the abscess cavity by fæcal matter is clearly a serious factor in connection with the history of these cases The great mortality from pelvic abscesses opening spontaneously into the bowel demonstrates the inability of nature to provide for adequate drainage Whatever question, therefore, we may raise relative to the advanced position of Dr Wm H Byford, who, if practicable, would prefer to open a pelvic abscess through the rectum—even in those cases in which nature has not anticipated him—there can be no question about the propriety of enlarging and rendering more effective an opening already formed He regretted that the essayist had marred a most admirable contribution by the sweeping statement that in all cases in which drainage has been spontaneously established through the rectum Lawson Tait's operation is contraindicated Nor can he imagine from what premises he has formed the conclusion that Tait's operation prevents closure of the sinus between the abscess cavity and the rectum The question naturally arises, whether Tait's operation might not in such cases fulfil a well recognized surgical indication by establishing a free counter opening for an abscess which otherwise might refuse to close on account of imperfect drainage and on account of its forming a blind sac for the retention of fæcal matter To a larger number of recognized authorities, who deem an opening into the rectum, whether produced by nature or by art, a grave misfortune, the query would naturally arise whether such an opening ought not to be supplemented by a counter-opening, which would bring the draining and cleansing of the abscess cavity within the easy and absolute control of the surgeon Furthermore, in view of the decided mortality which attends the spontaneous opening of pelvic abscesses into the rectum, and in view of the almost uniformly successful results recorded in the statistics of Tait's operation already published by Mr Tait and others, and in view of a very generally accepted rule that the operator, in opening a pelvic abscess, should strive to keep out of the rectum, he does not think a statement that the rectum is to be preferred as the site of a primary operation ought to go on the records of this Society unchallenged

---

[1] Lawson Tait op cit

Dr J T Jelks (present by invitation) thought a great mistake was made in waiting too long before operating in cases of chronic pelvic abscess

Dr Philip Adolphus thought the paper was beyond the pale of criticism When the general symptoms indicated a collection of pus, the cavity should be searched for If a cavity containing serum was found, an operation was contraindicated If the cavity contained pus, it should be evacuated

Dr H T Byford, in closing the discussion, objected to the quotation of Lawson Tait's statistical triumphs in this connection In the last edition of Tait's *Diseases of the Ovaries*, abdominal section is recommended for those pelvic abscesses only that cannot be successfully evacuated from below They are generally such as are situated high up, and do not point early in the vagina or rectum, or they are suppurating hæmatoceles The statement that the recto-abdominal fistula, left after abdominal section for a pelvic abscess that has already discharged into the rectum, would heal readily, like any artificial anus, is not borne out by facts Fistulæ connecting the rectum with the external air have seldom healed, when left to themselves, before a long period of time had elapsed Operative measures cannot (in these cases) be resorted to, on account of the length, situation and relations of the fistulous track

GYNÆCOLOGICAL SOCIETY OF BOSTON.

Stated Meeting, December 10, 1885

THE PRESIDENT, HENRY O MARCY, M D,
IN THE CHAIR

H J HARRIMAN, M D, SECRETARY

Dr J C Fox, of Lowell, presented

A SPECIMEN OF MULTILOCULAR OVARIAN CYST, LARGELY SOLID,

which he had removed a few hours before The tumor was of six months growth, and was diagnosed as a solid tumor Dr Fox was of the opinion, however, that it was ovarian and cystic The operation verified this latter diagnosis Patient was 47 years old But slight hæmorrhage followed the operation

Dr Warner asked Dr Fox the grounds upon which he had based his opinion that the tumor was ovarian and cystic

Dr Fox, in reply, said that in this case the uterus was of normal depth and was movable In fibroids he almost invariably found that the uterus was increased in depth and more or less fixed Dr Fox also cited a case of ovarian tumor of nine months growth which he had removed Four weeks prior to the operation excessive pain and vomiting suddenly came on Diagnosis of twist in the pedicle was made and verified by the operation The tumor was covered with lymph from inflammatory action, and was discolored and almost gangrenous from interference with its circulation Recovery

The paper of the evening, by Dr A Martin, of Berlin, on

THE TREATMENT OF CICATRICES IN THE COLLUM UTERI AND IN THE ROOF OF THE VAGINA,

(see page 198) was read by Dr C W Cushing, who also showed microscopical sections illustrating the pathological conditions of which the paper treated

Dr Warner did not fully agree with the sentiments so ably set forth in Dr Martin's paper He felt that the tendency of modern gynecologists is to exclude all treatment except operative measures At least many surgeons seemed to neglect all constitutional and mild local treatment in favor of the knife, ignoring and having no faith in drugs If this tendency becomes general the physician who is not a surgeon will have little to do except to be a looker-on in the practice of gynecology, while in reality more can be done with drugs in the way of local and constitutional treatment than can be accomplished with the knife He asked the gentlemen present what had been their experience in regard to the operation for repairing rents and cicatrices of the cervix, as far as concerned relief of symptoms previously complained of As far as he knew but few had been relieved by operation, as practiced here, of any of the symptoms of which they suffered Agreeing with Dr Martin that the rent was not of importance nor yet the cicatrix without a diseased condition of the cervical mucous membrane, he insisted that such diseased condition with the accompanying erosion and eversion of the cervical lips is caused by an irritating discharge coming from the cavity of the body of the uterus Unless the disease of the fundus is cured, and the discharge stopped, it will do no real good to sew up the cervix If the disease of the fundus with its acrid secretion is cured, however, the repair of the cervix is unnecessary, as the erosions can be healed, the eversion diminishes, and the patient gets practically well Dr Warner recognizes the wisdom of Dr Martin in attacking the disease of the fundus by a thorough curetting at the time of the operation, which, for as skilful an operator as Dr Martin, and in his own well appointed hospital, is doubtless a good treatment If Dr Martin, however, rested at the curetting without repairing or amputating the cervix, he would find that the patient could be healed without further operation

Dr Warner insisted that hereabouts, however, many gynecologists practiced operations for repairing the cervix without attacking the disease of the body, and that, perhaps from lack of skill and advantages of Dr Martin He had known of many bad cases of cellulitis, etc, caused by the operation without cure of the disease He playfully likened such incomplete treatment to excision of a section of the eroded upper lip in boys who do not keep their noses clean, and thought the latter operation not countenanced by surgeons

In answer to a question as to the proper treatment Dr Martin said that for curing the endometritis he was not able, in a few minutes, to gives rules covering all cases, as it was, above all, essential to consider the circumstances of each case, in a general way he relied largely on a proper regulation of the functions of the intestines and liver, and locally in the judicious use of iodine, acid carbolic, or even, in some cases, of acid nitrate of mercury As for erosions and eversions, the latter are usually kept up by cysts in or under the surface, sometimes pretty deep, these must be punctured and then the erosions heal easily under stimulating or sometimes escharotic applications, swelling disappears and the patient gets well, provided the endometritis has been cured, and not otherwise For the acrid discharge from the fundus is strong enough to cause not only erosions of the cervix, but also of the vagina, and in bad cases of the labia, thighs and abdomen, removing this cause the effects are easily cured

Dr E W Cushing defended the views which Dr Martin had set forth in his paper in regard to the pathology of these cases He asserted that there was no real erosion of the epithelium in those cases where the epithelium seemed to be absent, but that the gland tissue of the cervix which is normally limited to the mucous membrane or its immediately subjacent layers, increases to such an extent as to invade the other tissues This process sometimes goes on to such an extent as to lead to glandular degeneration of the entire thickness of the cervix In such cases he maintained that Dr Martin's operation was the only one which promised success—showing the hopelessness of the ordinary stimulating treatment often employed Dr Cushing exhibited several sections which, under the microscope, illustrated the pathology of these cases, he also showed sections of the pieces which Dr Martin had removed from the lips of the cervix He also showed the instruments with which Dr M operates, and by reference to the text book of the latter, which he brought with him, and by figures on the board, explained the details of position, etc, and the manner of employing antiseptics and enforcing surgical cleanliness, which enable Dr Martin to get such results Dr Cushing also referred to the danger that the glands, which grew with such rapidity, invading tissues where they do not belong, may in chronic cases begin to increase at such a rate as to be really malignant growths

Dr W S Brown thought the paper a valuable one, but feared that too much emphasis was put upon the *surgical* treatment of these cases He did not agree with those doctors who do so much surgery In his hands the majority of these cases yield to milder measures, such as thoroughly scraping the affected parts by means of the dull or sharp curette This method of treatment had yielded better results than local applications of carbolic acid or iodine In some cases, however, excision is the only efficient treatment When minute cysts are present in the cervix they must be punctured Proper constitutional treatment is of great importance and should never be overlooked

Dr Marcy said that twenty years ago in the Rotunda Hospital, at Dublin, the routine treatment of these cases consisted of applications of nitrate of silver in strength varying from 20–40 grs per ℥i This treatment of these lesions by local applications was slow and painful, and the profession has drifted into the surgical treatment of these cases

FOREIGN CORRESPONDENCE

LETTER FROM VIENNA

(FROM OUR OWN CORRESPONDENT)

Puerperal Fever—Statistics of the Lying-in Clinic—Laceration of the Perineum—The Enthusiasm in Austria over the Congress

In the Vienna school puerperal fever is known as septic infection, depending (1) upon the local lesion, (2) the infection of these local lesions Then follow (1) high fever and inflammation of the genitalia, (2 peritonitis, or pyæmia There are three varieties recognized *First*, Puerperal peritonitis, or puerperal endometritis, with a symptomatology of fever, unclean lochia, meteorismus, vomitus, and peritonitis Post mortem section shows *endometritis consecutiva*, salpingitis and *peritonitis purulenta*, with exudations *Second* Puerperal metro phlebitis or pyæmia without peritonitis, the septic virus passing through the placental insections to the uterine veins As symptoms we have High fever, chills, torpor, subinvolution of the uterus The abdomen is flaccid and painless on percussion There may be icterus and metastatic phlegmon *Third* Peritonitis plus pyæmia, or *lymphangitis uteri*, or *phlegmona pelvis septica*

The treatment is local when a woman begins to have fever on the second day *post partum* The external genitals and vagina are washed with a 1 2 per cent carbolized water, or with a 1-5000 sublimate solution When operations have taken place, and the lochia are pathological, and there is high fever, the uterus is irrigated, a glass tube being used Iodoform bacilli, containg 5-6 grms of iodoform, are placed in the uterus The formula used is

℞ Iod pulv	18 parts
Amyl puræ,	
Glycerinæ,	
Gum arabic	aa 2 "

Make 3 bacilli 5 6 ctm long Ice applications to the abdomen are used in *peritonitis incipiens* Ergot is used internally The antipyretics used are quinine, 1-2 grms daily, sod salicyl, 3-4 grms daily, antipyrin, 1-2 grms daily If these do not avail, the cold bath is resorted to Alcohol is used freely in pyæmia, but *never* in peritonitis In incipient peritonitis the following treatment obtains Ice pills, ice cataplasms on abdomen, opium by the rectum, and quinine by rectum In puerperal ulcers local applications of iodoform, or of iodol (which is expensive but devoid of odor), are resorted to Salicylic amylum (1 part of salicylic acid to 5 parts of amylum), has also its merits It has been found that the cases of puerperal metro-phlebitis, although attended with metastatic transference of the poison, forming abscesses and involving the lungs themselves, tend, in a large per centage of cases, to recovery, while those cases of puerperal peritonitis almost always end fatally Women seemingly moribund, in whom the whole system is poisoned, begin to recover as soon as elaborate metastatic action obtains These patients are given alcohol very freely.

Dr Emil Ehrendorfer (Ueber antiseptische—locale—Behandlung in der Geburtshulfe, *Archiv f Gynak*, Bd xxvii, heft 2), writing of the statistics of the Lying-in Clinic here, for the years 1882, 1883 and 1884, has furnished us with some very interesting data In 1882 the puerperal mortality was 0 51 per cent, in 1883 0 33, per cent , and in 1884 it was 0 32 per cent —this including three cases of Cæsarean section Puerperal fever in 1882 occurred in 4 31 per cent , in 1883, in 3 59 per cent , and in 1884, in 3 08 per cent , while other pathological diseases resultant upon labor fell from 6 17 per cent in 1882 to 4 87 per cent in 1884, and all this from a strict attention to antiseptics and cleanliness in every possible detail In these matters few people have a riper experience than Dr Ehrendorfer As first assistant to Prof Spaeth he is responsible every year for about 3000 labors

One is very much struck here with the rarity of perineal lacerations The matter becomes plain, however, when one sees with what tact the perineum is handled during labor The woman rests on her back until the head presses upon the vulva, then she is turned upon her left side, with the buttocks resting upon the edge of the bed, the legs well drawn up and kept apart either with a pillow or by an assistant The nurse sits on the right side of the bed, with her back to the face of the patient, the left hand is passed over the right thigh of the patient, and manipulates the child's head, the free right hand of the nurse keeps the perineum moist with carbolized water, and assists the left hand The patient is enjoined not to bear down, and the head is kept back forcibly, so as to prevent a too sudden birth The fingers of the left hand are occasionally run around the presenting part of the fœtal head, just inside the labia, or the head is gently moved toward the symphysis by a well directed action of the left hand The main thing is to keep the perineum moist and to keep the head back If there is thinning of the perineum, and a danger of laceration either lateral or bilateral, episiotomy is resorted to If there be immediate danger of a central rupture, an incision is made from the posterior labial commissure, creating a laceration of the second degree, which is operated on immediately after labor Lacerations of the first and second degree, and even sometimes of the third degree, are operated on immediately after the birth of the child, except when the woman's condition contra-indicates such a procedure For all minor lacerations serres fines are used I have seen several cases of hydramnios lately, and apart from other methods, the curves made with the women in different positions are quite sufficient to distinguish this condition from others which may simulate it

The enthusiasm here over the Congress grows daily, and I am quite sure that Vienna will send a large delegation to Washington I hope to be able to establish equal interest in Buda Pest and Munich I trust that the Executive Committee will publish full details, list of officers, modes of transit, arrangements for finding lodgings upon arrival, with the rules governing scientific papers to be read, in the leading medical journals of all the large European capitals At the meeting of the German Medical Society in Strassburg last September, members of the local committee met each train upon its arrival Large signs were placed in the station pointed towards a room in the station where the delegates could receive addresses of boarding-houses or hotels, together with prices and all necessary details Similar arrangements should be made at both stations in Washington, so that every member, upon arriving, could be directed at once to such a place as he desired The Secretary General of the Congress could also have assistants at the station, so that members could register immediately upon arrival, and receive all necessary instruction

DOMESTIC CORRESPONDENCE

LETTER FROM NEW YORK

(FROM OUR OWN CORRESPONDENT)

The Charity Organization Society—Hydrophobia and its Treament—Dr Edson's Report—Gift to the College of Physicians and Surgeons — Death of "Aunty" Dubois—Permanent Drainage in Ascites—The State Medical Society, Officers for the Year

The fifth annual meeting of that admirable body, the Charity Organization Society, was held at Association Hall on February 1 It has done a vast amount of good by caring for the wants of the de serving poor, providing employment for those able to work, exposing impostors, suppressing street begging and discouraging indiscriminate alms giving The Society now has on file 100,661 reports, containing the names and histories of 71,332 families—equivalent to 285,000 persons, and one great benefit which it offers to the various medical charities is that by means of its well organized investigations these institutions can ascertain whether the patients applying to them are really deserving of gratuitous treatment or whether they are able to pay for medical attendance As long, however, as an institution like the New York Hospital makes a charge of one dollar a month for each patient treated in its outdoor department—thus making these people feel that they are not charity patients at all, and directly robbing the profession every year of large sums which they would otherwise receive from a class perfectly able to pay a fair compensation for medical services—there is perhaps little chance of accomplishing much in the way of reform as regards the abuse of medical charity On the occasion in question, among the speakers was the Rev Dr Wayland, of Philadelphia, who made a striking comparison of "the old charity and the new" The old charity, he said, saw a woman with a diseased child on the sidewalk, and gave her money As a result, in a few days there was a premium for diseased children on the street The new charity, as represented in this Society, gave the sick child into careful hands, put the mother in jail, and suppressed a nuisance The Charity Organization Society now has 1,084 members, 483 of whom have been received in 1885

At a recent meeting of the Clinical Society of the New York Post-graduate Medical School and Hospital, a discussion on *Hydrophobia and its Treatment* constituted the order of the evening, and in the course of it Dr W A Hammond said that when proper precautions had been taken within a reasonable time after a bite by a rabid dog, he had never known the disease to occur Many cases of persons bitten by dogs supposed to be mad had come under his observation, and the first thing that he did under the circumstances was to take steps to ascertain, if possible, whether the dog really had rabies or not If he had, or there was any doubt about the matter, he excised or cauterized the edges of the wound, first having applied a cupping glass to the part, or caused the patient or some one else to apply his lips to it and suck out the poison, the virus being innocuous unless there was some abrasion of the mucous membrane of the mouth He also applied ligatures in cases where this was practicable It had always been his opinion that the disease could be communicated to a human being only by means of the saliva, and thereore he was inclined to doubt the efficacy of the process practised by M Pasteur, but still he did not feel in a position either to deny or affirm the value of the alleged discovery until further investigations of the subject had been made

The statistics of reported deaths from hydrophobia in this city during the last fifteen years are as follows In 1870, three, in 1871, seven, in 1872, six, in 1874, five, in 1876, five, in 1877, four, in 1878, 2, in 1881, three, in 1882, two, in 1883, one, in 1884, one, and in 1885, one, occurring in the month of October

The annual report of Dr Cyrus Edson, Chief of the Second Sanitary Division, shows that during the year 1885, 7,000 specimens of milk were examined, and 1,701 quarts of milk destroyed by the officers of the Board of Health There was also ordered destroyed 72 700 pounds of candy, 540 pounds of head cheese, 546 pounds of poultry, 37,905 pounds of canned goods, 5,160 pounds of cheese, 4,000 pounds of pickles, 4,100 pounds of coffee, 790,410 pounds of meat, and 212,000 pounds of fruit The trial of Gen Alexander Shaler on a charge of bribery in connection with the selection and purchase of armory sites for the city, came off on the 26th and 27th of January, but the jury were unable to agree, and a new trial will be held at the next term of the Court of Oyer and Terminer, which begins February 15 It is stated that the jury stood ten for conviction and two for acquittal

Mrs William D Sloane, one of the daughters of the late Mr Vanderbilt, has emulated her father's generosity to the College of Physicians and Surgeons of this city by the gift and endowment, in connection with her husband, of a free maternity hospital, to be conducted under the auspices of that institution It will be a handsome building of brick and terra cotta, in the new college grounds, and no pains will be spared to make it a model structure of the kind Although the maternity will be under the control of the Faculty of the College of Physicians and Surgeons, its business arrangements are to be in charge of a distinct board of managers, consisting of five gentlemen The first board will consist of the President of the College, Dr John C Dalton, *ex officio*, Mr Wm D Sloane, representing the donors, Mr Cornelius Vanderbilt, representing the College board of trustees, and Professors James W McLane and Francis Delafield, representing the College Faculty

"Aunty" Dubois, a colored woman, believed to have been the oldest person in the State of New York, has just died at Newburgh on the Hudson, at the alleged age of one hundred and ten years She was born a slave in Ulster County, N Y, and was for many years the property of one of the Ulster County Dubois families, being freed at the time when the last few remaining slaves in the State were emancipated One of the venerable negress's sons, who resides in this city, is said to look even older than his mother did at the time of her death

At a meeting of the Academy of Medicine held on February 4, Dr M A Starr read a paper on *The Intra Cerebral Tracts—their Physiology, and its bearing on the Diagnosis of Lesions of the Centrum Semiovale*, after which Dr A G Caille read one on *Permanent Drainage in Ascites* Dr Caille related two cases of cirrhosis of the liver with marked ascites, in which he had inserted a drainage-tube into the peritoneal cavity at the linea alba, with the result of affording great relief of all the distressing and dangerous symptoms, and probably prolonging life for a considerable period In one case an autopsy could not be secured, but in the other one was made, when it was found that there was not the slightest indication of peritonitis at the point where the fistula was made No internal treatment was used in these cases other than a careful regulation of the diet, and the administration of acid phosphate

The President, Dr A Jacobi, in commenting on the paper, remarked that the procedure resorted to by Dr Caillé was an imitation of the method sometimes employed by nature in these cases It was not very uncommon to see in extensive ascites a spontaneous fistula established at the linea alba, or, more frequently, at the umbilicus, and he related an instance of this kind which had not long since been under his observation at the German Hospital He also related a case in which, after hearing of Dr Caillé's plan of procedure, he had inserted a drainage tube in the same way through an artificial opening in the abdominal walls, and he said that he considered this likely to form a very valuable addition to our present modes of treatment As to the medicinal treatment of cirrhosis of the liver, there was one agent in which he had by experience learned to place considerable confidence in a certain proportion of cases, and that was mercury It was well known that in many instances the interstitial hepatitis was only partial, instead of involving the entire extent of the organ, just as was the case sometimes in interstitial nephritis, myelitis and encephalitis In affections of this kind it was always a source of congratulation to the practitioner to find they were of syphilitic origin, on account of the prospect that relief would be afforded by appropriate treatment, but he had now become satisfied that in non-syphilitic cases also, if the trouble did not involve too large a portion of the organ there was often a fair chance of curing the patient by a course of mercurial treatment He had been taught to look with utter abhorrence upon the use of mercury, and for many years he never employed it at all in any form except in syphilitic cases, on account of its supposed injurious effects upon the system But during the last ten or fifteen years he had resorted to its administration with very good effect in the class of cases referred to It was necessary to select some preparation which could be given in small doses and kept up for a prolonged period, and he was in the habit of employing the bichloride This might be given largely diluted, in solution, but he preferred the pill form One-thirtieth of a grain three times a day was about the amount that would usually be required, and the patient should be instructed to use a chlorate of potash wash and carefully watch the condition of his gums

There has been quite a stirring up of dead bones in the old State Medical Society, which held its annual meeting in Albany on the 2d, 3d and 4th of February, occasioned by the remarkable success and the scientific interest of the first two meetings of the energetic young State Association Extra efforts are made to secure a full gathering of the clans, and the number of physicians in attendance, as well as of the scientific papers, a fair proportion of which were by men of prominence in the profession, was unusually large Among the papers was one read by Lawson Tait, of Birmingham, on "Methods of Diagnosis" The President, Dr Albert Van der Veer, of Albany, delivered the annual address in Assembly Chamber in the Capitol on Wednesday evening, February 3d, taking for his subject "The Water Supply of Cities and Villages," the conclusions arrived at in which are the following Water needed for domestic purposes should be taken, first, by gravity from mountain streams, lakes or springs, next, if the former is not possible, provided the surroundings are safe and proper in every respect, by the Gang syphon driven wells, next by a system of storage, so arranging the reservoirs that proper aeration can be employed, and, lastly, if necessity compels that it must be taken from sources known to be polluted, then a thorough system of filtration should be resorted to, and the water be as completely oxygenated as possible before distribution

The following officers were elected for the ensuing year on the last day of the meeting President, Dr Wm S Ely, of Rochester, Vice-President, Dr Sol. Van Etten, of Orange county, Secretary, Dr Wm Manlius Smith, of Onondaga county, Treasurer, Dr Charles H Porter, of Albany The following honorary members were also elected Lawson Tait, F R C S, Birmingham, England, Dr E N Bush, of Philadelphia, Dr James G Richardson, of Philadelphia, Dr F Hansen, of Copenhagen, Denmark

P B P

"THE STUDY OF MEDICINE AS A MEANS OF EDUCATION"

To the Editor of the Journal

Dear Sir—Allow me to say to your numerous readers that the paper on "The Study of Medicine as a means of Education," which you have honored with an editorial criticism, (see Journal of January 9, 1886) was read only in abstract, the original paper being much too long to be read in a limited period of time or to be printed at my own expense This will account for the apparent disproportion of space given to some features of the subject Moreover, the indirect method of argument has its disadvantages, but it also has some advantages As a literary production the essay is certainly defective, and yet I have received several very complimentary letters in relation to it from men in the highest positions in the profession There are yet a few copies for distribution among those who may be interested in the subject and who may apply to the undersigned

In this connection permit me to add a word in relation to the origin and mission of the American Academy of Medicine in which the paper was read It was organized in Philadelphia in 1876, when the State of Pennsylvania was grievously afflicted with fraudulent medical schools, at a time too, when it was impossible to obtain anything more, as a means of protection, than *bogus* medical legislation Thanks to a daily newspaper, the *Philadelphia Record*, for effecting, by the use of means known only to the secret service of the government, what the profession was not able to do, though several attempts had been made And thanks to the Illinois State Board of Health for a more systematic exposure of the nefarious traffic in medical diplomas It was organized, we say, when there was scarcely a ray of hope for the profession in Pennsylvania, when there were at least 2000 medical practitioners in the State, as is shown by recent registration, who had either no medical degree or had purchased one from these schools, and what we have still to regret, is this, that the greater part of them remain in our midst It is not too much to say that our legislature, our medical societies, and our medical journals were under the influence of these institutions and classes of practitioners A large representation of these were always in our legislature, and they assumed to know what were the wants of the professsion and the people The exposure came, however, and they could no longer face the odium Other States were passing through a similar experience, but certainly not so shameful

In the organization of the Academy under these circumstances, it was thought best to require for membership at least one academic degree besides the degree of doctor of medicine Whether such degrees may be invariably required will depend entirely upon the majority in the Association It may be truly said that degrees, either literary or medical, have very little signification, as regards mental capacity, education or professional skill This much, however, may be said in their favor, that they are conferred by independent groups of men representing institutions of learning which have a reputation to maintain They should certainly not be made the only test for membership in an educated body of men Those who have passed creditable examinations in the army and navy, and many others, should certainly be admitted

The Academy would scarcely have a reason for an existence were it not for the wide-spread evils to which we have referred It can never be more than a help in the profession, and should be welcomed as such The encouragement of a higher standard in which all its members may join, is its special work, but there is no good reason why any topic pertaining to medicine or to the medical profession should not be discussed in it

An objection may arise in the mind of some, that the Academy is based upon "classical, scientific, and literary schools" and courses of study in them This is indeed the fact, but it is also true that our profession is based upon these schools and courses of study whether we recognize it or not These schools were formed by our fathers, and they simply accepted the experience and judgment of educated men in other countries than ours It is plain that young men must get their education in these institutions, such as they are, or go without an education The medical student will never amount to much until he has spent ten or twelve years at very faithful and patient study at something, and I am shut up to the conclusion that he had better spend *half* this time in classical, scientific, and literary schools in laying a good foundation With the permission of the Editor of The Journal, I may some day express myself more fully on these topics

Very truly,
R Lowry Sibbet, M D

Carlisle, Pa , Feb 11, 1886

[It must be apparent that we could not give our correspondent credit for that portion of his paper which was not printed, we naturally presumed that we had the entire article before us when we wrote If the reader will turn to our editorial article in The Journal of January 9, p 43 *et seq* , it will be seen that we have not criticized the objects of the American Academy of Medicine, but the requirement for membership that the applicant must be a graduate of an academic college It will also be seen that we did not criticize the literary merits of the article, nor can we agree with the author that it is "certainly defective" from a literary point of view Our whole criticism was leveled at the pernicious doctrine that a man *must* have a *classical* education, and a diploma from a classical college, before he is fit for the study of medicine (or any other profession) Our correspondent's article, as it came to us, contained no mention of the value of "classical, scientific, and literary schools," it referred to classical schools only And while it mentioned the value of mathematics and the languages, it contained no reference to the value of scientific studies It is not entirely correct to say that "classical, scientific, and literary schools were founded by our fathers " Our fathers and grandfathers founded *classical* schools, but none which deserve the names "scientific" or "literary" Nor have our fathers (or we) "accepted the experience and judgment of educated men in older countries than ours " Their dogmas have been accepted without question, along with much bad judgment, and those of us who pin our faith to classical studies are flying in the face of experience instead of accepting it, for, unfortunately, having experience and being guided by it are very different matters We will be pleased to have Dr Sibbet give his views on these topics at any time —Ed]

THE RECENT MEETING OF THE PHILADELPHIA COUNTY MEDICAL SOCIETY

To the Editor of the Journal

Dear Sir —In the issue of your journal for January 30, your Philadelphia correspondent enters somewhat fully into the history of the last business meeting of the Philadelphia County Medical Society He speaks of "the informally presented candidates " Now in order that it may be fully understood how nominations for delegates from this Society to the American and State Medical Societies are made, I will quote part of Art XII, Section IV of the By Laws which reads as follows "At the stated meeting in June, a committee of five members shall be constituted, two of whom shall be appointed by the President, and the remaining three elected by ballot, which shall be called the nominating committee At the stated meeting in October, this committee shall present a ticket of candidates for election to the different delegations of the Society "

This committee was constituted in the manner prescribed by the By-Laws, and made their report at the stated meeting of the Society in October, which report was accepted The "informally presented candidates" which your correspondent speaks of, were nominated in secret caucus by a self-constituted committee, composed of members unknown to a large part of the Society This list of "informally presented candidates" had never been seen by those of the Society who were not supposed to be in accord with them until the day of election, when it was read, and by methods heretofore unknown to the Society made to take the place of the ticket proposed by the legally constituted nominating committee

So anxious was the self constituted committee to make a ticket to suit their purpose, that they placed in nomination two who were not members of the Society, and twenty-four others who were not eligible as delegates under the By-Laws when the regular nominating committee made their report

The nominating committee, although constituted in the regular way, was accused of being packed, and of packing the delegates for both the American and State Medical Societies in the interest of the action of the American Medical Association, at its last session in New Orleans It has been ascertained since the election, that twenty of those nominated in the regular list for the American Medical Association, voted for the "informally presented candidates," twenty for the regular ticket, and five could not be accounted for This does not look much like a packed ticket in the interest of a faction

I regard the course pursued by that part of the Society in opposition to the regular ticket as uncalled for and the precedent established a dangerous one for, the best interest of the Society I will not allude to the great interest taken in the meeting, of which your correspondent speaks, further than to state, that the proceedings were of a character entirely unbecoming to a body of medical men

MEMBER OF THE NOMINATING COMMITTEE
Philadelphia, Feb 11, 1886

MISCELLANEOUS

SPHYGMOGRAPHY IN A BALOON — Ascensions in baloons are now so frequent that we are in possession of many of the physiological phenomena that attend the sudden alteration of pressure M Pozzi has taken some tracings with the sphygmograph at a height of 2150 metres A rapid rise with brief maintenance and rapid descent, disturbed by well marked dicrotism, were the chief features of the sphygmogram The peculiarities are, in relation with the lowering of arterial pressure, due to the sudden rarefaction in passing to the higher strata of the atmosphere They form the counterpart of the experiments of Viveriot with compressed air —*The Lancet*, Jan 23, 1886

TYPE WRITING AS A HELP TO MEDICAL MEN — A correspondent of the *British Medical Journal* calls attention to the value of the type writer as a help to medical men who write "In these days of high-pressure, when every moment is of the greatest value, and must be made use of, any invention that will tend to save those golden moments will be hailed with satisfaction by those who feel that they have so much to accomplish in their short span of life One of these time saving instruments is 'type writing,' and it has been recognized as a great boon by all who have made use of it Authors of all kinds require printed proofs of their work before it finally appears as a readable book, and in most instances 'press corrections' form a serious item in the bringing out of a book But it is especially to the medical man who has papers to prepare for reading at meetings, lectures, etc , short articles to send to medical journals, that this method of copying will commend itself He can at once see how his written matter will look in print Papers that are to be read out at a meeting are, we are informed, more easily deciphered when printed in the plain, clear type of the type-writer than even the neatest handwriting"

REVOCATION OF LICENSE FOR UNPROFESSIONAL CONDUCT —In the case of the State *ex rel* Chapman *vs* State Board of Medical Examiners, etc , the Supreme Court of Minnesota have recently held that Sec 9, c 125, Gen Laws 1883, entitled "An Act to regulate the Practice of Medicine in the State of Minnesota," which provides that the "Board of Examiners may refuse certificates to individuals guilty of unprofessional or dishonorable conduct, *and may revoke their certificates for like causes*," is constitutional The revocation of such certificates is not the exercise of judicial power, and hence may constitutionally be vested in the State Board of Medical Examiners

M JULES GUERIN, one of the most distinguished physicians and scientists of France, and the founder and for many years the Editor-in chief of the *Gazette Medicale de Paris*, recently died at the age of 85

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY, FROM FEBRUARY 6 1886, TO FEBRUARY 12 1886

Major Henry A Tilton, Surgeon (Ft Wayne, Mich), granted leave of absence for two months, to commence on or about March 1, 1886 S O 8, Div Atlantic, Feb 9, 1886)

Major H E Brown, Surgeon, granted leave of absence for six months, on surgeon's certificate of disability, with permission to leave the department of the Missouri (S O 29, A G O , Feb 4, 1886)

Capt Rob't H White, Asst Surgeon, granted leave of absence for two months, to take effect when his department commander may think proper (S O 29, A G O Feb 4, 1886)

Capt Wm C Shannon, Asst Surgeon, ordered for duty at Ft Warren, Mass , relieving Asst Surgeon John M Banister, who will return to his proper station (Ft Adams, R I) (S O 27, Dept East, Feb 6, 1886)

First Lieut Guy L Edie, Asst Surgeon, ordered for field duty in New Mexico with troop "K," 8th Cav (S O 23 Div Mo , Feb 8, 1886)

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING FEBRUARY 13 1886

Crawford, M H , P A Surgeon, detached from the "Shenandoah" on the 8th inst Wait orders

Rush, C W , Asst Surgeon, detached from the "New Hampshire" on the 15th inst , and ordered to U S R Str "Franklin"

DIPHTHERIA IN THE CITY OF KALAMAZOO, MICHIGAN, IN 1884

BY H B HEMENWAY, A M, M D,
LATE HEALTH OFFICER OF KALAMAZOO

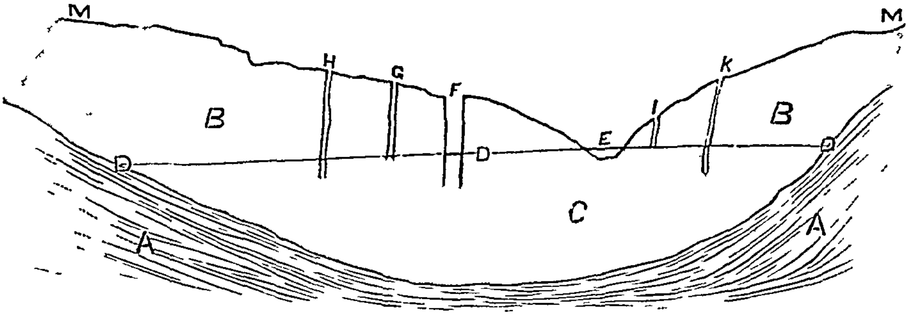
To the physician three fields of work present themselves, in which he may spend his time and strength He may devote himself to the study of the normal and morbid conditions of the human system, simply for the satisfaction received in learning, he may direct his attention to the cure of diseased bodies, or, his thought may be occupied in discovering and making known the cause of sickness

There is, perhaps, no other one disease about which there is so much disagreement among doctors, as diphtheria It is not my intention here to discuss especially the identity or non identity of diphtheria, and membranous croup Neither do I propose to look for those minute forms of life, which one sees so clearly, and another observer says do not exist, save in the mind of the enthusiast Nor shall I ask the reader to investigate with me, at present, whether we should give to the patient brandy or quinine, turpentine or calomel, ice in the throat or hot applications I shall endeavor to give facts as they were, uncolored by any pet theory or idea When an opinion is stated I shall seek to so express it that the reader will at once be able to separate the true from the possibly false

During the latter part of the year 1884, there occurred in the city of Kalamazoo, Michigan, a large number of cases of diphtheria At first they seemed to be to a degree sporadic Though in some localities several persons were ill, yet no connection could be found between the disease in one section and that in another Before proceeding, however, to give a history of the epidemic, perhaps a general view of the city would not be unprofitable

Kalamazoo is a beautiful little city of about 15,000 inhabitants, located in the midst of a rich farming region It nestles in a hollow, with hills nearly surrounding it The river, from which the place took its name, runs into the city from the east, twice turns back upon its course and then runs northward until beyond the limits of the corporation Though hills have been mentioned, there is no marked elevation of the earth's surface The river flows silently, and the wind may easily sweep any street in town Two creeks join the river within the city walls At the "Ox bow" an old settler cut a canal across a narrow neck of land, and located a flour mill, using his canal for a race He needed no pond as the river furnishes all the power needed without any special storage of the water Just south of the city the stream is divided A portion flows on in its natural channel, the remainder is conducted along higher land to run another mill Before it gets to this mill the race expands into a storage pond Along this larger creek, and around the "Ox-bow" of the river, the land is low, and in the springtime it is often covered with water North of the city the valley spreads out to the width of three quarters of a mile The soil of most of this low land is a rich alluvium Mixed with the mould is more or less sand, and an occasional bowlder is to be seen Here, too, are peat beds, which furnish a good grade of that fuel The centre of the city is built upon higher ground, which, like the surrounding hills, is composed largely of sand In some places so much clay is mixed with the sand that the earth is very firm In others, the sand may be found in a pure state Under the whole city, from six to twenty five feet below the surface, there is a bed of clay This is not very thick in any place, though its thickness varies greatly At the paper mill a short distance south of the city, an attempt has been made to get an artesian well The drill went down between 750 and 760 feet below the surface For about 200 feet the workmen bored through all kinds of drift material, mingled sand, gravel, clay, and bowlders At that depth a small stream was struck, but it did not flow with sufficient force to answer the purpose The water had a decided taste and smell of coal oil A little more than 200 feet from the surface shale was reached As far as the drill went below that point nothing but shale was found, and at last the enterprise was abandoned

A study of the geology of this section of the State shows that Kalamazoo is situated nearly in the centre of a large depression in the rock This basin, about seventy five miles in diameter, and nearly round, is filled, as has already been mentioned, with gravel sand, and other drift material Reference to the cut may aid the reader to understand the elements of the water supply of the city This figure is of course schematic, and drawn without reference to proportion, as the ratio of the diameter of the basin to the depth of the same is many times greater than one might infer from the diagram Imagine, then, AA to represent the bed rock, and MM the surface of the ground BCB would then represent the drift material The water level would be practically the same (DDD) for the whole basin, with an outlet (at E) in the Kalamazoo river At the depth of C there would be little to produce motion in the water, it would be without special current More water, therefore, coming into the basin in the form of rain or sewage would, as soon as it reached the water level, tend to flow out towards E Theoretically, therefore, and actual tests show it to be a fact, the water at the water level would not be as pure as that from a greater depth There are three sources or modes of water supply for the citizens Open, or dug wells, drive wells, and the city pumping works This last water is commonly known by the name of the first pumps used at the works—Holly The source of this water pumped by the city engines is a deep well (figure, F), so constructed that the water only enters from the bottom Among the dug wells I included what many call spring water For example, in case 130, to get drinking water a barrel was sunk in the ground by the side of a ditch Strange to say, at the level of the water in the ditch the aqueous fluid was to be found in the barrel To make the work as easy as possible, the point selected for lowering the barrel was where the surface came nearest to the water level The water to be had from wells on the hill in the northwest corner of the city is purely surface water, as it comes from above the clay stratum already mentioned Many of the drive wells do not go down deep enough to gain the advantage of drive wells, as they only give surface water



The present system of sewage was adopted in December, 1880 The first sewers put down were laid the next summer During the summer of 1884 the work of laying the lateral sewers was pushed vigorously, and at the close of the season about twelve miles of pipe had been laid In 1885 the work was again pushed forward The system adopted is essentially that of Col Waring Only a very small percentage of the residences had been connected with the public sewers at the time of the outbreak of diphtheria The Arcadia creek, which flows through the centre of the city, was an open sewer An ordinance was passed during the year forbidding its use as such In the older portion of the city the ground is full of cesspools, many of them long since forgotten

There is a large Dutch population in the city In their native country they were accustomed to live on low land, and here they settle where most people would not think of locating their houses All around on the flats one may see their little huts and cottages Some of these are kept as clean as any house could be, many are less wholesome, and some are decidedly filthy They are decided fatalists When the attention of a mother was called to the filthy water drank, as the cause of her child's diphtheria, she replied, "No water! It comes from Himmel" Their children are put to work almost as soon as they can walk The soil where they live is well fitted for celery raising The shipping season lasts about six months To give a little idea of the amount of that article raised one need only state that it is not an unusual thing to ship forty or more tons of celery in a single day, sending it to the Atlantic and Pacific Oceans and to the Gulf of Mexico The women and children do much of the washing and preparing for shipment They will often stand all day with their hands in cold water at this labor In more than one instance children have been sent out to this work before they were entirely well

Kalamazoo is not a very unhealthy place The estimated number of deaths for the year 1884–85 was about 12⅔ per thousand Omitting the deaths from diphtheria and other so called preventable diseases, the rate would have been 8 per 1000 In 1884, from the 7th day of May to the 21st of June, there was no grave opened in the Protestant portion of the city cemetery, and from May 26th to June 21st there was no interment in the whole cemetery In June, 1885, there were only ten burials in the city

We are now prepared to study the earlier cases of the epidemic, and then study the outbreak as a whole

Case 1 —F, aged 3 years, only child Parents both deaf mutes Family live on the upper floor of a frame house The Arcadia creek, above mentioned, flows through the back yard The creek is higher than the cellar floor The little girl was reported ill with scarlatina about the last of April As health officer I visited the place and confirmed the diagnosis Ordered the father, who was a mechanic employed in a furniture factory, to remain at home I ordered them to keep the child as perfectly isolated as possible The house was in a good condition generally The cellar was damp, and the mother informed me that, a day or two before, the baby played down cellar for some time She attributed her sickness to that She was quite sure the child had not played with other children A few days later, on April 29, the attending physician reported that the scarlatinal symptoms had nearly left, but that he had a clear case of diphtheria just developed that day There had been no known case of diphtheria in the city for several months The family could not conceive of any means by which they might have come in contact with that disease The case progressed favorably and in two weeks was reported recovered, but on May 20 the doctor was sent for in haste, and when he reached the house the child was dead, probably from cardiac paralysis The family used water from a dug well, and there was no sewage for the house A baby under one year old in the same house did not get sick

Cases 2, 3, and 4 —F , F , and M , aged 10, 4½, and 2, living about six blocks from case 1, all came down with diphtheria on July 20 The house inside was in good sanitary condition The sink-pipe emptied upon the surface of the ground near the house, and the filthy water stood there until absorbed by the ground Six feet from where the water struck the earth a drive well entered the ground A microscopical examination of the water from this well showed large quantities of organic matter A former occupant of the house "could not live in Kalamazoo on account of her health" On July 25 the mother of these children was taken with diphtheria. The use of the well water was stopped, and all except case 3, which died of septicæmia, recovered I could not trace these cases to a previous case

Cases 6 and 7 lived just around the corner from the preceding, and had played with them before they were taken sick They were taken sick on July 26 and 30 respectively Case 6, F , aged 8 years, lived in an old house, which sat down on the ground, without cellar wall, and which showed marked signs of decay Both these families used dug wells, and neither place had sewage

Case 8 —Colored, M , aged 12 years, was taken sick August 1st Lived in an old house without sewage Used dug well Could not trace this to any preceding case

Case 9 —M , 15 years old, lived in the south-eastern portion of the city (The others were all north of Main street) Could not trace the case to preceding cases House near marsh land, and no ventilation under the rooms where he lived Taken sick August 5 Died August 24 of cardiac paralysis

Case 10 —M , aged 3, taken sick August 16th, and *Case 11* —F , aged 7, taken sick August 17th, lived in the north eastern portion of the city in an old house without other foundation than the earth A hole in the ground was called a cellar, and there the winter's wood was kept, and the bark and sawdust accumulated Could not trace to other cases

Cases 12 to 17, inclusive, were colored children, in two houses, and though I could not trace them to case 8, yet they may have taken the disease from him The sanitary condition of their homes was very poor Three of these cases died

Case 18 —M , 12 years old, was taken sick September 28 He had always been sickly The family lived on the third floor of a tobacco store Used Holly water and city sewage Traps imperfect, alley in the rear not in good condition Died suddenly from rupture of an abscess in the pharynx Could not trace to previous case

Case 19 —Could not be traced to previous cases Used water from dug well Sewage of place nil House old and decaying

Case 20 —Mild case Lived in second story of a store building Private drain, Holly water, private alley in rear in very bad condition just before the boy was taken sick, slops were thrown out into that alley by neighbors and allowed to stand upon the ground until dried up

Of the next two cases I simply recorded "bad surroundings" Though I could find no communication with case 19, yet they may have taken the disease from him More likely they might have all three taken the disease from case 25, though I think they did not do so

Cases 23 to 25, inclusive, and 35, ages 5, 2½, 9, and 7, sex, F , F , M , M , taken sick September 18, 18, 15, and 22 The house was a small frame structure of one story The cellar walls were made of two layers of boards, between which sawdust was packed In the spring the cellar floor was covered with water No attempt had been made to ventilate the place The sawdust was moldy and mushy In the cellar were the remains of vegetables not less than a year old The boards around the door-way were quite rotten There was no provision for the care of slops, but the tidy housewife stepped upon the back porch and threw her dishwater, etc , upon the surface of the ground The dug well had partially caved in, on account of the giving away of its wooden walls, and consequently the surface of the ground sloped towards the well The water from the well was used for cooking and drinking All the children in this house were sick The boys, who were away from home more or less, were but slightly affected The girls, who had been in the house much, were very sick, and the older one died Next door to this family lived another, whose sink-pipe opened upon the surface of the ground among a lot of weeds From the street both of these places looked very neat and clean I examined the weeds and found that the ground was a soft slime several inches deep There was a window over these weeds about five feet from the ground By this window a child slept She had diphtheria. The family used a dug well under the house

Not to be burdensome I will only make a few more selections

In *Case 40* the drinking water used was very bad

Cases 55, 56, 58, 59, 60, F , M , F , F , F,, aged 3 years, 15 months, 12, 14 and 15 years First three fatal Taken sick October 6, 8, 6, 1, and 2, respectively The three older children were sent out peddling vegetables after they were taken sick No physician was called until the night before the first child died Upon examination I found a dug well close by the back door The kitchen had no floor but the ground On two sides of this kitchen was a ditch, eight inches deep, which served to receive and hold the family slops It did not conduct them away

When I reached the house this ditch was full of black water The well was not six feet from this ditch, and yet the mother wondered that the health officer would not allow her a couple of weeks before having that ditch filled up

In another house upon the marsh, with ditches around, and those ditches dammed to help the celery, there were four children, the oldest 11 years old, and the youngest 18 months All died except the baby The baby was not sick In this case a dug well was used, and I found the women standing upon the well platform pouring their slops off from its edge

In *Case 163* a young lady fell into the fire and was very seriously burned One of the attending surgeons was at that time attending a case of diphtheria The general sanitary condition of the house was good

In one house, old and without sewage, dug well, and no cellar or chance to ventilate under the house, there were eleven cases and seven deaths

Case 215—A beautiful little cottage was built on ground that had been used for a long time as a dairyman's cow yard A well was dug not more than fifteen feet from the privy Soon after the family moved into the cottage the little girl was taken sick

In a few cases I could find nothing about the premises in a bad sanitary condition That, however, was no proof that the disease might not have arisen from filth The physician reporting case 69 recorded as the source of contagion "unknown" The patient was a butcher, 36 years old His children were playing with him and even kissing him after the disease was clearly defined, and yet he was the only member of the family attacked The neighbors had complained of his barn yard, but the health officer did not think it probable that Mr F had taken the disease there Examination of the meat market showed that right under where Mr F stood at his work, there was a water closet in the cellar The sewer pipe was broken and leaked both water and gas In another instance (from my own practice) a family lived in a new brick block of four houses Everything seemed to be in good condition until I asked the owner about the sewer traps I then found the following condition There was a large and good cesspool of brick behind the house, and only twenty feet from the building There was an opening at the surface of the ground for ventilation and cleaning Four lead pipes connected this cesspool with the four kitchen sinks There were *no traps*, but the pipes were as straight as possible The pipe to No 3 was the shortest and straightest Since the upper end of the pipe was several feet higher than the out-of doors ventilator of the cesspool, very naturally in kitchen No 3 there was frequently to be detected an odor of sewer gas In this house, all three children had diphtheria without being exposed to any previous case so far as known Traps were at once put into each sink pipe No other children in the block had the disease

In most families where the first cases were promptly isolated other persons were not attacked

Table I gives a synopsis of the water supply and sewage of the first 292 cases I may here express a regret that I did not keep a fuller account of all the cases Whoever has attempted, however, to keep statistics of this kind readily realizes how difficult it is to get accurate information, and how often the statistician receives an intimation that the information sought is none of his business

TABLE I

WATER SUPPLY AND SEWAGE

	TOTAL		FATAL		Percent of Cases Fatal
	Number	Per cent.	Number	Per cent	
WATER—					
Holly	53	18	13	21	24 53
Drive Well	101	35	10	16	9 90
Dug Well	137	47	39	63	28 47
Cistern	1				
SEWAGE—					
Cesspools	33	11	5	8	15 15
City Sewers	6	2	2	3	33 33
No Sewage	253	87	55	89	21 74
TOTAL	292	100	62	100	21 23

About twenty five per cent of the entire population of the city use the Holly water Since only eighteen per cent of the diphtheria patients used that water, it seems to indicate that they are less likely to take the disease on that account Probably there are other reasons besides the kind of water drank why these citizens should be less prone to the disease A very large proportion of the cases occurred among the poor population, especially among the Dutch

In regard to the portion relating to sewage, it must be noticed that the places where no provision had been made for the care of kitchen slops are decidedly the most prolific of cases, and fatal cases The very small number of cases in which the premises are connected with the city sewers renders the last column of that line of little value One of the two fatal cases was No 163, already mentioned, in which the injuries received nearly took the patient's life, before the diphtheria attacked her As relating to the subject of sewage, it may be noticed that no cases occurred upon the east side of the river until the dams on the river were fixed, and the water raised enough to overflow some low land there After that there were nineteen cases, six of which were fatal

After a careful study of the epidemic, I came to the following conclusions

1 Diphtheria is essentially a filth disease

2 It may be produced without any relation to a former case

3 During the earlier stages it is but feebly contagious

4 A simple "sore throat," including under this head tonsillitis, pharyngitis and laryngitis, may develop into diphtheria, without receiving contagion from a previous case

5 Diphtheria, after being once produced, may become contagious and epidemic

6 Diphtheria and the proneness to the disease may be modified by the constitution of the person, and by atmospheric conditions

7 Diphtheria and membranous croup are the same disease

To what extent does one attack protect from future attacks? I regret to say that I have no accurate data on this subject Some persons were attacked a second time On the other hand, in one family of four children all but one had the disease some years ago This year this one had it and died Those who had had it before escaped this year

What relation has age and sex to the disease? Table II gives the number of cases of males and females of each age from April 15, 1884, to July 1, 1885 For study the cases are divided into four groups Those under 6 years old, those from 6 to 10 inclusive, those from 11 to 15 inclusive, and those over 15 It will be noticed that almost ninety two per cent of the males, eighty five per cent of the females, and eighty eight per cent of all cases were under 16 years old

Average Age—Males 9 03 Females 10 67 Total 9 94

A Age *N* Number *M* Total Number *P* Percent of Cases

Table III shows that ninety three per cent of the males, ninety five per cent of the females, ninety-four per cent of all cases proving fatal were under 16 years of age Of the cases over 23 years old, all but four occurred in families where there had been previous cases among the children Among the four is the butcher mentioned as Case 69 One was an old colored woman who had not had any child sick with it so far as known, but she lived in the neighborhood of cases among the negroes Of the fatal cases over 15 years old, the boy of 16 was an unusually well developed lad The girl of 17 was also well developed So far as could be seen there was no special reason why they should either of them die The girl of 18 was the one already twice referred to as having been severely burned The man 33 years old had pneumonia His four children had diphtheria, and three of them died After the last death he caught cold, and at the same time diphtheria took hold of him, almost immediately extending through his entire lungs It will also be noticed that more girls than boys were attacked during the first period In the next the boys are most numerous During the years when the maidens are preparing for womanhood they are again more likely to be troubled by the disease

In the first year of life there were 13 cases—8 males and 5 females, at 2 years there were 16 cases—4 males and 12 females, at 3 years there were 24 cases—9 males and 15 females, at 4 years 26 cases—11 males and 15 females, at 5 years 25 cases—13 males and 12 females, at 6 years 24 cases—14 males and 10 females, at 7 years 34 cases, equally divided, at 8 there were 21 cases—11 males and 10 females, at 9 there were 26 cases—16 males and 10 females, 23 cases in the 10th year included 11 males and 12 females, 17 cases at 11 were divided among 8 males and 9 females, 15 cases at 12 included 5 males and 10 females 7 cases at 13 included 2 males and 5 females, 9 cases at 14 showed 3 males and 6 females; 12 cases at 15 give 4 males and 8 females, 5 at 16 give 3 males and 2 females, 3 at 17 show 1 male and 2 females, and at 18 there were 2 cases, both females

The age at which death took place in the fatal cases was as follows At 1 year 3 males and 1 female, at 2, 6 females, at 3 years 4 males and 4 females, 4 males and 7 females at 4 years, 2 males and 4 females at 5, 4 males and 1 female at 6, 1 male and 3 females at 7, 2 males and 4 females at 8 1 each at 9, 2 females at 10, 1 each at 11, 1 male and 2 females at 12, 2 females at 13, one each at 14, 1 male and 2 females at 15, 1 male at 16, 1 female at 17, and 1 female at 18

A Age *N* Number *M* Total Number *P* Percent of Fatal Cases
T Percent of all Cases

It will be noticed that 7 seems to be the favorite age for patients It will also be noticed that boys reached their highest mortality for any age at the years 3, 4 and 6, losing four at each of those ages The girls lost seven at the age of 4 Table III shows that the mortality of females was greater than that of males What is the influence of weather upon diphtheria? Table IV gives the weather report, and number of new cases of diphtheria each week for the last six months of 1884 I often noticed that when the amount of ozone dropped to one or two for two or three days, new cases would be reported, and old ones were likely to be worse At Christmas time there was considerable snow upon the ground, and there were but two or three cases of diphtheria The snow melted quite suddenly during the next few days, and within two weeks there were twenty-five new cases reported When the ground had been frozen a short time the number of cases was small

TABLE IV

Week ending	New Cases	Bar	Ther	Wind	Cloud	Ozone	Rain
July (fraction) 5		29 091	70 25	3 85	5 08	2 00	0 22

Table giving for each week the number of new cases of diphtheria in the city the average barometric pressure thermometer (F) velocity of wind amount of cloud ozone and rainfall (Cloud and ozone marked on scale of 10)

Of the fatal cases, the modes or causes of death were as follows

Cardiac paralysis	8 cases
Laryngeal stenosis	29 "
Septicæmia	27 "
Laryngeal stenosis and septicæmia	4 "
Rupture of abscess	1 case
Hæmorrhage (from bowels)	1 "
Total	70 cases

So far as known, of the cases reported one had the membrane only in the larynx Three or four females had the membranes over the genitals Several had the membrane upon abrasions of the skin I think that, without exception, cases in which blisters had been raised progressed towards recovery more slowly, and were more liable to septicæmia than those not so treated In several cases the parents had applied kerosene oil to the neck externally, before the physician was called At first, knowing that some good authorities had recommended that vesicants be used, I permitted my patients to be so treated, though I did not recommend it but I became thoroughly convinced that the practice did much harm

Though, as before stated, I do not propose to discuss the subject of therapeutics, yet it may not be out of place here to say that I think, with only one exception, all the physicians here use some preparation of mercury in the treatment of this disease Some prefer as a general thing the iodides, others the chlorides Especially in robust children, my own preference is for the mild chloride, given in 2-grain doses, every two or three hours until six powders have been taken for a child 5 years old The one physician above mentioned depends largely upon whisky and quinine His success certainly is not better than the average Within the last year various papers have recommended the burning of tar and turpentine I think those who have tried it here will not try it again For laryngeal trouble, however, some have thought they were aided by the vapor of turpentine I used it in one case with good results The turpentine was put into boiling water, and the patient inhaled the steam Noticing the tendency towards cardiac paralysis, from the first I gave all my cases digitalis, and after the fever began to subside I administered tr nucis vomicæ Locally I used a solution of carbolic acid or permanganate of potassium Though I did not try it, I think the mixture of solutions of corrosive sublimate and permanganate of potash would do good, better, indeed, than any other application I have seen suggested Personally I am convinced that ice applications are detrimental, but I allow the patients to drink water freely Alcohol is good, but it must be used with caution I am convinced that we must study to prescribe such medicines as will not disgust the patients, as not infrequently serious results have followed the resistance of the patient against taking the drug prescribed

The patient's strength must be kept up, not by stimulants, but by food When all else fails I depend on milk, given, if necessary, in dram doses every half hour Since most of the cases occurred among the poor and more ignorant population, where they did not receive, and could not get competent nursing, it was the opinion of the attending physicians that if we had had a city hospital where such patients could be cared for, from forty to fifty per cent of the fatal cases would have been saved, and the whole number of cases would have been diminished

In what proportion of the cases did paralytic symptoms develop? I could not tell exactly, as physicians made no report of paralysis except incidentally I knew, however, of a dozen cases out of the 331 There probably were more One of these was almost entirely paralyzed, and afterwards recovered In two cases at least, the paralysis developed certainly a month after apparent recovery took place One of these proved fatal

I am under obligations to Mr A M Munn, of the Michigan Asylum for the Insane, for kindly giving me free access to his weather record The observations were made by Mr Munn at the Asylum, which is situated upon the hill in the southwest portion of the city

Kalamazoo, January 10, 1886

BRAIN TUMORS[1]

BY PHILIP ZENNER, M D ,

LECTURER ON NERVOUS DISEASES IN THE MEDICAL COLLEGE OF OHIO
CINCINNATI

Our present knowledge of cerebral localization lends additional interest to the study of all cerebral lesions This statement is least applicable to neoplasms They have less value than other kinds of lesions in forwarding our knowledge of localization This is the more to be regretted, as it seems probable that brain tumors will soon be relegated, in part at least, to the domain of surgery

Large and even multiple tumors may be almost latent, while small growths may produce marked symptoms In one instance a tumor may produce symptoms, and in another not, when in precisely the same part, and the symptoms may be altogether deceptive The factors which determine the symptoms produced by a tumor are

Its location
Its size
Its character, density, vascularity, etc
The rapidity and manner of its growth
The extent of destruction or softening of nervous substance

These bear a certain relation to the kind of tumor Cysticerci are of a soft consistence, and never destroy the brain substance Carcinoma, tubercles and some others usually destroy neighboring nerve tissue Too many elements, however, come in play to enable us to diagnosticate the kind of tumor from the cerebral symptoms alone Brain tumors cause pressure by general increased pressure, and by their direct influence on the nervous tissue They may destroy brain tissue, produce softening of the parts around, or cause symptoms by direct compression In order to produce the local compression the tumor must be harder than the brain substance The compressing effects also depend on the locality of the tumor If it be on the convexity, the brain may accommodate itself to the growth without sustaining any local injury while at the base, where each part is to a certain extent fixed by the cranial nerves and blood-vessels direct local compression is easily produced Each nerve found at the base is represented by a comparatively large area of the cortex at the convexity, so that a considerable lesion in the latter locality is requisite to produce the symptoms made by a small one in the former Furthermore, it appears that when a part of the cortex has been destroyed another part will sometimes perform its functions The tissues next to the bone or rigid membrane are, *cæteris paribus*, compressed to a greater extent than the central part of the cerebral lobe, which is everywhere surrounded by soft brain substance Paralysis of the olfactory nerves is often produced by compression of the nerves between the brain and frontal bone, so that loss of smell occurs with brain tumors quite independent of their locality The third, sixth, and other cranial nerves have also been affected in the same manner

The heightened intra cranial pressure may also paralyze the nerves by causing them to be constricted where they pass through the tightly stretched dura mater, or to be compressed by distended blood-vessels It may even produce hemiplegia or other focal symptoms quite regardless of the seat of the tumor Such occurrences occasion great confusion, and hence it is well for us to remember this rule That local or localizing symptoms are the less valuable for the purpose of making a local diagnosis the more marked are the symptoms of heightened intra cranial pressure

The most prominent symptoms of heightened intracranial pressure are headache, convulsions, double optic neuritis, vertigo, vomiting, changes in the pulse and in the mental condition But even these symptoms have a certain local significance The headache points to the direct or indirect involvement of the dura mater, the convulsions to the motor areas of the brain, the mental symptoms to the cortex, the vertigo to the cerebellum, vomiting and alterations in the pulse to the medulla Each of these parts may become affected when there is increase of the general pressure Headache occurs most frequently when the sensitive dura mater is most easily affected, convulsions when the motor area is most readily irritated

These symptoms occur most easily when rapid changes occur in the tumor, for instance, rapid growth or transient fluctuations

Headache is the most common and usually the earliest symptom The pain is frequently of the greatest intensity, often driving the subject wild It is then most likely to occur in paroxysms, though it not uncommon to find even the milder headache cease altogether for a longer or shorter period of time If the pain be quite circumscribed, and constantly in one place, it is likely to point to the seat of the tumor. Usually the pain is not circumscribed, and, except neuralgia of the fifth, is of no value in locating the tumor It is a singular fact that the headache often diminishes or disappears when paralytic or other focal symptoms occur The growth of the tumor is probably very slow in those cases in which no headache occurs

Convulsions are a less common symptom than headache, but occur in nearly half the cases They have a greater local significance than the headaches

Double optic neuritis is also a common general symptom, and of all is the most nearly pathognomonic. It probably occurs in the majority of cases, but is sometimes a transient condition

Vomiting due to brain tumor is usually distinguished from that due to the stomach by its occurrence equally, whether that viscus be full or empty, and by the slight subjective symptoms accompanying it

Mental symptoms, apathy, loss of memory, somnolence, etc , usually occur at a late period though they are rarely absent

Intercurrent apoplectic attacks are usually due to hæmorrhage in or about the tumor

The chief localizing symptoms of brain tumors are paralysis of the cranial nerves

Tumors of the brain must be diagnosticated from abscess and meningitis, but usually other concomitant conditions will lead to a correct diagnosis

---

[1] Read before the Cincinnati Academy of Medicine on Feb 1, 1886

In the medical treatment, apart from opium as a narcotic, iodide of potassium is by far the most valuable drug It has been said to effect cures in tumors which were not syphilitic But it seems probable that in the near future operative interference will be often resorted to in these cases, and it is worthy to consider farther this aspect of treatment As an operation for the removal of a tumor is chiefly thought of in reference to those on the convexity, I may here consider what symptoms might assist us to a proper diagnosis of these tumors Among these may be mentioned headache, monoplegia, aphasia and hemiopia These symptoms under very favorable circumstances may lead us to correct local diagnosis of tumors at the convexity But we must never forget the rule that the value of localizing symptoms is in inverse proportion to the indications of heightened intra-cranial pressure Wernicke has suggested tapping the ventricles for the purpose of reducing the intra cranial pressure

A symptom very common and frequent is blindness from atrophy of the optic nerves, caused by pressure of the accumulations of the third ventricle which is again usually due to a tumor in the posterior fossa of the skull, most frequently tumor of the cerebellum Therefore, blindness setting in rapidly and at an early period is a symptom of much localizing value, and not only is it of diagnostic significance but provided tapping of the distended ventricles should prove serviceable, it would be a valuable guide in treatment It would indicate to us cases which could at least palliate the symptoms which it would be a great triumph to relieve Those symptoms are most prominently blindness, often deafness, some headache and other general symptoms of increased intra cranial pressure

A CASE OF SARCOMA OF THE LOWER JAW, SUCCESSFUL REMOVAL[1]

BY OSCAR J COSKERY, M D,

PROFESSOR OF SURGERY IN THE COLLEGE OF PHYSICIANS AND SURGEONS BALTIMORE, MD

Peter King, colored, aged 15, born in Maryland, was admitted into the City Hospital, Baltimore, on March 31, 1882 His family history was good His personal history was as follows Between two and three years ago his mother had first called his attention to a generally enlarged condition of the left side of his lower jaw, and a consequent swelling of that part of the face This became more and more apparent, the growth was recognized by his medical attendant to be confined to the inferior maxilla, and as it spread in every direction, the teeth had been displaced and the tongue pushed well over to the right About two months before he came under my observation an enlarged gland had made its appearance in the left submaxillary triangle, which frightened the patient, and decided him to have all removed if possible

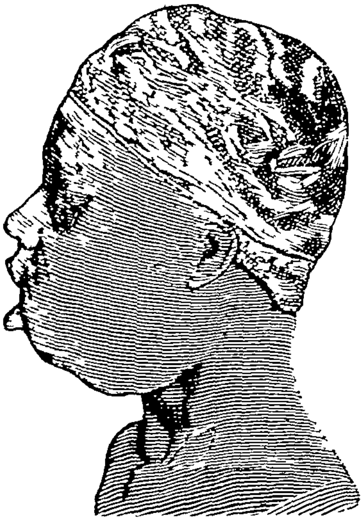

FIG 1 —Cast of face and head before operation

On April 15, 1882, the patient being fully under chloroform, an incision was commenced in the median line of the lower lip, cutting through the soft tissues to below the chin From this point the cut was continued over the most prominent portion of the tumor, first outwardly as far as the angle of the jaw, and then upwards to its point of articulation with the temporal bone The flap being dissected off, was turned up, and the growth exposed In this step of the operation the facial artery was cut, and required ligation The right median incisor was now drawn, and the metacarpal saw applied to the jaw just to the right of the symphysis menti As soon as the bone was sawn through it was seized in the left hand, and its soft connections with the floor of the mouth quickly severed Then, without attempting the more dangerous task of disarticulating the head of the bone with the knife, strong traction was made upon it, and the neck gave way The bone forceps were applied and the head of the bone, together with the remainder of the neck, were wrenched from position

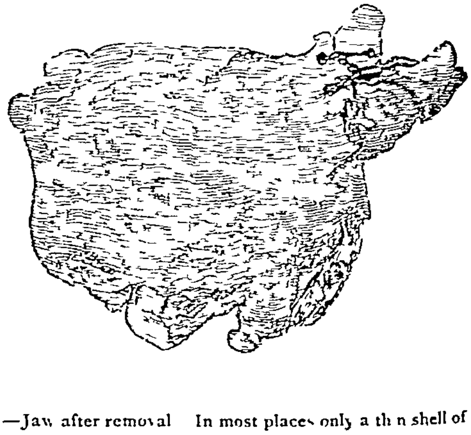

FIG. 2 —Jaw after removal In most places only a thin shell of bone

---

[1] Read in the Section of Dental and Oral Surgery at the Thirty-Sixth Annual Meeting of the American Medical Association

Up to this time the hæmorrhage had not been very great Upon cutting down upon the enlarged gland and enucleating it (which was done with ease), very profuse venous bleeding came on, and it was found that a large branch of the external jugular had been cut The vessel required ligation at both ends The skin flap was then brought into position, room near the angle of the jaw being left for drainage, and dry lint was applied upon the wound, a bandage over all

The boy did well from the first To keep down the fetor of the discharge "Listerine" was used throughout as a mouth wash The cut united kindly, and the patient left the hospital on May 6, 1882, or exactly twenty one days after operation, with only one suppurating point (that left for drainage), and with very little deformity

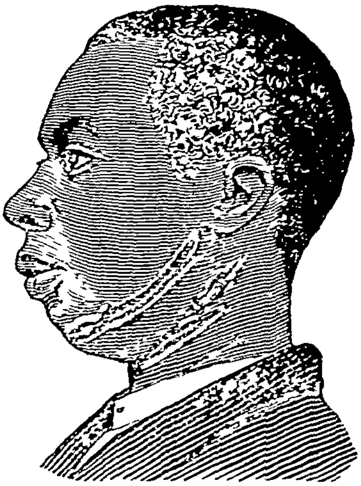

FIG 3—Half view of boy three years and a quarter after operation

Results of microscopic investigation (made and reported upon by Dr Aug Hoen of Waverly, Baltimore Co, Md) "Microscopically this tumor is made up mostly of a dense white fibrous stroma, staining badly with carmine, in some places this stroma presents dilatations of its fibres, which dilatations are filled with elements of the spindle variety only, in some of the dilatations they are very closely, in others loosely packed The cells all contain a single oval nucleus, surrounded by a moderate amount of protoplasm The fate of the cells seems to be their gradual transformation into the fibrous stroma above mentioned, constituting a true fibroid sarcoma, or recurrent fibroid of Paget Points of degeneration could not be discovered in any portion of the tumor, the tendency of the cellular seeming to be the production of fully formed and mature tissue"

P S—Since the above was written, I have been able to get photographs of the boy From the time he left the hospital he has been making a living as a farm hand The side view shows the fibroid thickening (cheloid?) so often noticed in the scars of colored people As will be observed, his general nutrition seems to be good

MEDICAL PROGRESS

THE PHYSIO-PATHOLOGY OF FEVER—MARAGLIANO has studied during the last three years the behavior of the vessels of the skin in beginning and in receding fever, with the hydroplethysmograph of Mosso, often eight to ten hours without interruption A first series of observations was made on patients who, in the course of the experiments, were spontaneously attacked by fever The main results of these observations were the following

1 A febrile temperature was found to be preceded by a progressive contraction of the vessels of the skin

2 During the height of contraction—when the vessels attain their minimum lumen—we find the climax of the febrile temperature

3 As long as the temperature remains at its highest level the contraction of the vessels persists

A second series of experiments was instituted on patients in whom the fever set in after a previous reduction of the temperature to normal by antipyrin, kairine, and thalline In these experiments Maragliano observed the same phenomena as stated above

In a third series of experiments patients were used in whom the febrile temperature fell to normal during the experiment without the exhibition of antipyretics The following results were here obtained 1 The fever attack is preceded by a progressive dilatation of the vessels of the skin 2 This dilatation increases simultaneously with the sinking of the temperature, and reaches its maximum when apyrexia appears

These investigations prove the old theory of fever as advanced by Traube Basing on the results of his calimetric examinations, Maragliano feels certain that in fever we have to deal with a retention of heat, with concomitant ischæmia of the vessels, and in defervescence, with an increased thermal discharge, with a concomitant vascular dilatation Still our author does not by any means believe that the retention of heat is the sole cause for the fever On the contrary, he is positive that still another factor viz, increase of heat-formation, plays an important rôle in the causation agencies of fever The increased production of urea and of carbonic acid gas furnish a satisfactory proof for the existence of this increased heat-formation As to the true significance of this intensified combustion process, we require a good deal more of detailed knowledge Possibly it is caused simply by an overheating, as it were, following upon the retention of heat

Naunyn, Lehmann, and others have recently shown that if animals are subjected to an artificially effected rise of temperature, they give off more urea and carbonic acid Maragliano has observed the same phenomenon in men if they are subjected to a heightened temperature, such as in consequence of warm baths

At any rate, there is no doubt that an increase in the heat-production takes place, no matter what causes the latter might have Therefore we can conclude that the rise of temperature in fever is caused by both a heat retention and an increased heat-production

This does, not of course, exclude the presence of other still unknown factors

The experiments and observations made in this connection on various antipyretic drugs are equally interesting

The first series of experiments were made with kairine, antipyrin, thalline, the salts of quinine, and salicylate of sodium, on individuals who were perfectly afebrile and healthy The results obtained with Mosso's hydroplethysmograph and Winternitz's calorimeter were as follows

1 All employed antipyretics cause in apyretic individuals a considerable vascular dilatation

2 They cause also an increased discharge of animal heat

3 They produce a fall in the excreted carbonic acid gas

A second series with these drugs was made on fever patients, and gave the following results

1 *The antipyretic effects of these drugs are caused* by a vascular dilatation When their influence is exhausted, vascular contraction and subsequent rise of temperature ensue

2 During the period of their activity increased discharge of heat invariably takes place After their exhaustion the heat discharge decreases, and the temperature rises again

3 The influence to antipyretic drugs is intimately connected with a reduction of the oxidizing processes within the economy

As a general conclusion to Maragliano's valuable researches, we can advance the theory that antipyretic remedies act by being able to eliminate the two most important pathogenetic causes of fever In other words, they prevent vascular contraction, and the thus resulting storing up of animal heat, and increase the heat discharge, besides, they combat successfully the increase of heat formation by reducing the intensity of the oxidizing processes of the economy

This double action of the antipyretic drugs is probably caused by an influence exerted on the innervation of the vascular system and the so called trophic nerves Possibly their action affects directly the medullary centres, which, according to the latest researches of Fano, exert a great influence on the nutrition of tissues —*Therapeutic Gazette*, Jan 15, 1886

TREATMENT OF PELVIC ABSCESS IN WOMEN —At the close of a paper on this subject DR PAUL F MUNDE draws the following conclusions

1 Pelvic abscess in the female is not very common, in proportion to the great frequency of pelvic exudations, and probably does not occur in more than ten per cent of all cases, the majority of exudations terminating in spontaneous absorption

2 Pelvic abscess may be either extra peritoneal, the result of cellulitis (by far the most common variety), or intra-peritoneal, the consequence of pelvic peritonitis If intra-peritoneal, the adhesive inflammation between pelvic viscera and intestines may so seal the abscess-cavity as to render it *practically extra* peritoneal

Abscess of the ovary and pyo salpinx do not belong in the catagory of "pelvic abscess" proper, and do not fall under the same therapeutic rules, unless when, by agglutination to the abdominal wall or to Douglas' pouch, they become virtually extra peritoneal

3 Small deep seated pelvic abscess, not exceeding a capacity of two ounces and minute multiple abscesses in the cellular tissue, can often be permanently cured by evacuating the pus thoroughly with the aspirator The surrounding exudation is then rapidly absorbed

4 About one half of the abscesses open spontaneously into the vagina, rectum, bladder, or through the abdominal wall and ischiatic fossa These cases may gradually recover without treatment, or the sinuses may persist until closed by surgical interference

5 Abscesses containing more than two ounces of pus should be opened by free incision along an exploring needle or grooved director, cleared of débris by finger or blunt curette, and drained and irrigated, if necessary, through a drainage tube

6 This incision should be made at the spot where the pus points most distinctly, which is usually the vaginal vault

7 In a certain number of cases the pus points through the abdominal wall, generally in the iliac fossa, and the incision should then be ample, and free drainage should be secured

8 When the pus has burrowed deep into the pelvic cavity, and a probe can be passed from the abdominal incision down to the vaginal roof, mere abdomino cutaneous drainage will not suffice, and a counter opening must be made in the vagina, and a drainage tube carried through from the abdominal wound into the vagina This drainage tube may have to be worn for months In making this incision, care should be taken not to wound the bladder

9 The opening of a pelvic abscess which points through the abdominal wall does not differ from, and is no more dangerous than, the same operation elsewhere on the cutaneous surface of the body It is not an "abdominal section" or a "laparotomy," in the sense that these terms are now used to indicate the surgical opening of the peritoneal cavity

10 Chronic pelvic abscesses, which have burst spontaneously, and have discharged through the vagina, rectum, or elsewhere for months or years, are exceedingly difficult to cure This is particularly the case when the opening is high up in the rectum A counter-opening in the vagina, or enlarging the opening if there situated, the curette, stimulant irrigation, etc , may occasionally succeed, but usually fail

11 A perityphlitic abscess may point through the abdominal wall, and simulate a pelvic abscess proper Aspiration will settle the diagnosis, the treatment is the same

12 The majority of cases of pelvic abscess recover, at least the mortality is small —*American Journal of Obstetrics*, February, 1886

THE USE OF UTERINE DILATOR IN THE TREATMENT OF DYSMENORRHEA, AND AS AN AID IN INTRA-UTERINE THERAPEUSIS —At the meeting of the Alumni Association of the Woman's Hospital of New York, on January 20, DR W GILL WYLIE read a paper on this subject The reader demonstrated his modified Sims' dilator, cervical protector, and hard-rubber cervical drain tubes, instruments which he was in the habit of using in dysmenorrhea, and for intrauterine medication He thought that dysmenorrhea was ordinarily dependent on a hyperesthetic state of the cervical and uterine mucous membrane, and the aim of the treatment was to allay this He urged the necessity of getting rid of all periuterine tenderness, and securing a movable uterus by means of glycerin tampons and hot water injections before resorting to treatment In simple cases of dysmenorrhea, gentle dilatation, repeated once a week for a while, accompanied by tonics, ordinarily sufficed Where there existed a spasmodic element, however, and where there existed sterility, he was in the habit of incising the cervix posteriorly down to the vagina, and then divulsing under an anæsthetic It was after this process that he placed his drain tubes in the canal, above the internal os, using them instead of a stem The tubes, being of hard rubber, could be heated and given the desired curve Thorough antisepsis should characterize every step of this operation He prefers this method to Goodell's rapid dilatation, because by this the cervical tissues are apt to be torn He has also found dilatation of value after the menopause, where on passing the sound, he determines a similar hyperesthesia at about the internal os

Dr W E Moseley, of Baltimore, did not believe that the aim of slight dilatation was accomplished as well by Wylie's dilator as by graduated conical sounds He had also noticed the utility of dilatation after the menopause, in cases where there existed slight dis charge, and nervousness, and stenosis at internal os For thorough dilatation he preferred Sims' trivalve dilator, occasionally paving the way for this by Wylie's In a personal case, which he related, Wylie's dilator had proved too weak to stand the applied pressure He believed that, through the trivalve dilator, the effect was more thorough, and less harm was likely to be done owing to the screw attachment for regulating the dilatation

Dr Goffe thought that dilatation was especially of value in case of sterility He much preferred, to rapid dilatation under ether, gradual dilatation once a week during the intermenstrual period

Dr B McE Emmet stated that he did not believe in obstructive dysmenorrhea, but that pelvic inflammation was at the bottom of every case Every case of dysmenorrhea was better treated by local applica tions to the vaginal vault, and constitutional treatment, than by dilatation, excepting, of course, where stenosis, the result of caustic applications, etc , existed As for intrauterine therapeusis, the uterine canal had better be left religiously alone The uterine mucous membrane is over treated when periuterine inflammation is at the bottom of symptoms

Dr Porter, of Providence, asked for information in regard to permanency of results, and as to how rapid the dilatation should be

Dr Wylie, in closing, said that the dysmenorrhea might return with impaired health, but that in ten years of experience he had not had a failure The hyperesthesia, the prime factor, is not likely to return Thought that very few gynecologists would agree with Dr Bache Emmet He stated that Sims gave up the trivalve and screw long before he died, and used the instrument which he (the speaker) had modified, mainly by curving the tips As for the danger from dilatation, there is none if proper antisepsis be resorted to The objection to conical dilators is that they are apt not to dilate where we wish, at the internal os —*Am Jour of Obstetrics*, Feb , 1886

Splenic Hypertrophy with Atrophy of Adrenals — Dr Robert Saundby, Physician to the Birmingham General Hospital, has just recorded, in the Transactions of the Pathological Society, a very remarkable case of hypertrophy of the spleen with atrophy of the supra renal capsules A young lady who was only 18 years of age when she died, had suffered for three years from dark skin, progressive anæmia, and gradual splenic enlargement She passed dark colored urine, but this had been habitual with her since birth This dark color was due to indican There was never any leucocythæmia or marked oligocythæmia, but the red corpuscles were deficient in hæmoglobin After death, which resulted from an attack of vomiting, of which the patient had had several at intervals, the spleen was found to weigh 66 ounces The supra-renal capsules weighed 18 grains and 10 grains respectively, and under the microscope showed simple atrophy of their substance So far the case may be regarded as one of Addison's disease, due to simple atrophy of the supra-renal capsules, of which Hadden, Coupland, and Barlow have published examples But the remarkable feature of this case is that the father died at the age of 37 with the same symptoms, and was found to have a spleen which weighed 7½ pounds, while a brother, still alive, presents the same series of phenomena. This coincidence suggests that the atrophy of the capsules has been in each case congenital—a view which is supported by the microscopical appearances of the capsules, in which no trace of inflammatory action was observed The enormous splenic enlargement present in all three cases distinguishes them from ordinary cases of Addison's disease, in which hypertrophy of the spleen, though frequently observed, reaches very moderate dimensions The fact that there should be this tendency, even in ordinary cases, to enlargement, indicates, in Dr Saundby's opinion, that these enormous spleens depend upon the long continuance and extreme degree of the capsular affection It is noteworthy that Dr Saundby could discover no change in the structure of the semilunar ganglia, and that, with the exception of pigmentary deposits, the organs generally were free from obvious alterations —*The Lancet*, January 23, 1886

Injections of Calomel in Syphilis —Dr Neisser, Professor at the University of Breslau, recom mends in the *Deutsche Medizinal Zeitung* of November 30, his method of employing calomel hypodermically He uses the following formula ℞ Hydr chlor mit , Sod chlor , āā 5 parts, Aquæ dest , 50 parts, and injects a syringeful twice every two weeks, or once every week, into the gluteal region, penetrating deeply into the tissues Neisser claims that on account of the long-lasting and yet but very slowly-proceeding absorption of the mercury, this method is alongside of the inunction-cure to be regarded as the most efficacious and energetic treatment of syphilis He has treated one hundred and twenty-two cases (fifty-four males and sixty eight females) with these calomel injections, and feels quite gratified at the results In rebellious and relapsing cases this method gave especially favorable results The objections that can be urged against these calomel injections are that they occasion a good deal of pain, and not rarely produce infiltrations and abscesses, which untoward effects, however, can all be avoided by an ample ingestion of chloride of sodium, either as *an addition to the food or taken alone*

The nozzles of the hypodermic syringes used in Germany are about one third longer than those used in America, and are buried in the tissues to their full length It is claimed that the danger of forming an abscess is lessened by entering the lowest strata of the connective tissue, or even the muscles themselves The method as practised in America, however, gives such satisfactory results that there is no occasion to deviate from it —*Therapeutic Gaz*, January 15, 1886

JOINT-DISEASE IN LOCOMOTOR ATAXIA —At the meeting of the Pathological Society of London, on December 1st, DR W B HADDEN read notes of two cases of joint disease in locomotor ataxy 1 A man aged 50, three years before admission, began to suffer from a swelling of the left knee, the swelling, after extending down to the ankle, subsided, but recurred in six months Two years before admission, ulceration occurred in the under surface of the right great toe Symptoms of locomotor ataxy had existed for three years On admission, in addition to the lesion already mentioned, there was a perforating ulcer of the right foot The femur was displaced forwards and outwards, the tibia backwards and inwards, the patellar was much enlarged, and there was a bony plate below it, pus was withdrawn from the knee joint by aspiration Amputation was subsequently performed, and, after two attacks of secondary hæmorrhage, he recovered Along the margins of the articular surfaces were numerous bony outgrowths, but the head of the tibia was the only part affected by atrophy, in the subsynovial tissue in front of the lower end of the femur was some new bone The only change noticed in the peripheral nerves was some (doubtful) thickening of the perineurium in the internal popliteal 2 A man who had suffered for many years from severe gastric crises Six years before he came under observation, the left shoulder became swollen, and subsequently pus was discharged When admitted, the patient presented well marked symptoms of locomotor ataxy, and there was atrophy of the anterior group of tibial muscles The left shoulder-joint was disorganized, and the humerus shortened About the right elbow and right knee joints were some bony outgrowths, and the capsule of the shoulder joint was dilated, and contained some bone Many pedunculated, cartilaginous, and osseous growths sprang from the interior of the joint, and some were found free in the joint The head and neck of the scapula had disappeared, and the head of the humerus showed pure atrophy The spinal cord showed sclerosis of the posterior columns, extending into the lateral columns, and also the anterior root-zone The postero lateral groups of cells at the level of the eighth cervical nerve on the left side had disappeared, and nearly all the motor cells at the level of the third lumbar pair of nerves In the first case, the knee was in a condition of osteo arthritis, the shoulder in the second was typical of Charcot's joint-disease The poliomyelitis of the lumbar cord was clearly the cause of the atrophy of the tibial muscles, but whether the atrophy of the motor cells in the cervical region was the cause of the joint lesion, or secondary, was doubtful The condition of the medulla oblongata lent some support to Dr Buzzard's theory

DR BUZZARD said that the second case, which had once been under his care, was a most remarkable example of gastric crises The presence of sclerosis in the medulla oblongata in close relation with the vagus root, was very interesting, and lent support to the theory he had put forward —*British Medical Journal*, Dec 5, 1885

ALBUMINURIA IN STRANGULATED HERNIA —J ENGLISCH, in the *Centralbl fur Chir*, Nov, 1855, publishes the history of twenty-nine cases of strangulated hernia treated by taxis, and of twenty five operated on In the first series he found albuminuria ten times in the urine, in the second twenty-two times In thirteen cases of hernia, accompanied by inflammation, albuminuria appeared twice Albuminuria appears as soon as intestinal occlusion reaches a certain period, and presents certain lesions, the more marked is strangulation, the more evident is albuminuria In partially strangulated hernia it is barely present When the omentum and appendices are strangulated, or a filled hernial sac is inflammed, albuminuria is altogether absent When there is gangrene of the intestine, albuminuria is very evident, it decreases slightly after operation In fatal cases it is more abundant Urine decreases in proportion as albumin increases English attributes death in strangulated hernia to renal disturbance, in those cases where the necropsy does not furnish any indication The albumin precludes any but a slight attempt at taxis, and herniotomy ought to be preferred *London Medical Record*, Jan 15, 1886

ANTIPYRIN AS A HÆMOSTATIC —DR E CASETTI, (*Raccoglitore Medico*, August, 1885, *Gazzetta Degli Ospitale*, September 30, 1885, *Nouveaux Remedes*, January 15, 1886) is said to have used four and five per cent solutions of antipyrin successfully as a hæmostatic in a case of epistaxis, in one of resection of the elbow, and in one of removal of a nævus He thinks it superior to perchloride of iron in not incrusting the surfaces, to the actual cautery in not leaving an eschar, and to ergotin in not being poisonous in ordinary quantities Its antipyretic effect, and probably its antiseptic action, are additional advantages —*New York Med Jour*, February 6, 1886

THE

Journal of the American Medical Association

PUBLISHED WEEKLY

THE EDITOR OF THIS JOURNAL would be glad to receive any items of general interest in regard to local events or matters that it is desirable to call to the attention of the profession. Letters written for publication or containing items of information should be accompanied by the writer's full name and address although not necessarily to be published. All communications in regard to editorial work should be addressed to the Editor.

SUBSCRIPTION PRICE INCLUDING POSTAGE

PER ANNUM, IN ADVANCE $5 00

SINGLE COPIES 10 CENTS

Subscriptions may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible remittances may be made at the risk of the publishers by forwarding in REGISTERED letters.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 65 RANDOLPH STREET

CHICAGO, ILLINOIS.

SATURDAY, FEBRUARY 27, 1886.

THE AMERICAN MEDICAL ASSOCIATION—IS IT DESIRABLE TO MAKE MATERIAL CHANGES IN THE PLAN OF ITS ORGANIZATION, PARTICULARLY IN THE DIRECTION OF ASSIMILATING IT TO THAT OF THE BRITISH ASSOCIATION WITH BRANCHES?

A letter in the issue of this JOURNAL for February 6, 1886, over the signature of "Branch," inviting attention to this question, has elicited several interesting letters from well known members of the Association, which we give in the department of Domestic Correspondence in the present number of THE JOURNAL. These letters contain many suggestions both for and against material changes that are worthy of careful thought.

It may appear to our correspondents, and, indeed, to most of the present active members of the profession, that the main question involved in this discussion is new, or broached now for the first time in connection with the organization of the American Medical Association. Such a supposition, however, is entirely erroneous, for it engaged the attention of the Committee appointed by the National Medical Convention assembled in 1846, and which reported the plan of organization of the permanent Association to the adjourned meeting in the following year in Philadelphia, and elicited full discussion both in the Convention and the first Session of the Association. The real question was, and still is, whether an efficient and general organization of the profession could be founded on a proper application of the principle of *representation* from local organizations to State, and from the State to the National as the union of the whole, or whether the National Organization should be self constituted, with provision for a broad nominal membership and a *Council* of lesser numbers invested with the whole management of the affairs of the Association, elected by itself, and consequently capable of self-perpetuation. The latter is the essential principle on which the British Association is founded, modified only by the formation of subordinate Branches, each permitted to elect one or more members of the general governing Council.

But the Committee appointed in 1846 to report a plan of permanent organization at the next meeting, after very careful consideration, rejected this principle and reported a plan of organization based entirely upon the representative principle, with a uniform numerical ratio to limit the number of representatives, and entrusting the entire control of the business of the Association to the regularly elected delegates that assembled each year, instead of to any more limited or select Council. It was claimed by those who advocated essentially the plan of the British Association, that the plan recommended by the Committee, having no provision for the election of a governing Council or any considerable number of members, but being dependent entirely on delegates elected annually by State and local Societies, would lack stability and be liable soon to crumble to pieces. On the other hand, it was claimed by a majority of the Committee and others that the creation of a National Organization with all governing authority vested in a limited number of members designated as distinctively *Fellows* or members of Council, elected mainly by the Association itself, and eligible to re election at stated intervals, was not in harmony with the modes of thought of our people, and would be likely soon to engender jealousies and rivalries both as to individuals and locations.

But much greater emphasis was placed upon the lack in such an organization of any active and powerful encouragement to the formation and support of State and more local organizations. While simple membership in the National Organization would be easy of attainment, without reference to membership in any local or State Society, one of the strongest incentives to the formation and active support of such societies would be lost; whereas, if membership in the National Association could be obtained only through membership in, and election as a delegate by, some regularly organized local Society, it would be constantly acting as a powerful incentive to the formation of such local societies in every part of our country, until at no distant time the great body of the regular profession would become embraced in social organizations—city, town, county, district and State, and from which delegates duly elected would constitute the National Society and make it truly representative of the profession of the United States. It is hardly necessary to state that the views of the Committee prevailed, and the plan of organization proposed was adopted with but little alteration. As there were at that time but few State Medical Societies in existence or in active operation in the States, provision was made for the admission of delegates from all legitimate medical societies, and institutions, including medical colleges, hospitals, asylums and infirmaries.

But the impulse given to the work of organization of the profession, by the successful establishment of the National Association, proved so efficient, that ten years had not elapsed before State Societies which had before been allowed to die were reorganized, and new ones organized in States where none had existed before, until regular State Societies and many of a more local character were in active operation in nearly every State in the Union. And the same active influence in sustaining and extending the affiliated local societies continues until the present time. The progress of events, however, soon developed the fact that the provision in the constitution of the National Association admitting two delegates from the faculty of each medical college, and one from the medical staff of each hospital, lunatic asylum, dispensary, etc., not only gave the medical men connected with those institutions a much larger number of delegates, in proportion to the whole number engaged in them, than were allowed to the society organizations, but it removed one of the strong motives for them to become members and efficient members in the societies in their own State. The fact that these men could go directly as (in one sense) self-elected delegates to the National Organization and become enrolled as permanent members, without any help from either county or State Societies, certainly removed one strong inducement for them to give active support to the latter. Yet by the public positions they held, it was claimed that as teachers, and hospital physicians and surgeons, they were preeminently qualified to impart most interest to all scientific work in the societies of their own localities. But whether conscious of the influence of this relation upon themselves or not, the fact became more and more apparent to others, until it eventually led to an amendment of the constitution by which the sending of delegates was restricted to regularly organized society organizations, thereby requiring the members of college faculties and the staffs of hospitals, etc., to gain admittance to the National Association through the same channels as the rest of the profession. To those who have been careful observers of the progress of events the change has not been without good results. We will reserve the further consideration of this topic for the next issue of THE JOURNAL. He is most wise who learns most accurately the lessons of the past.

MENINGITIS AS A COMPLICATION OF PNEUMONIA.

The testimony of competent observers has placed beyond doubt the fact that lobar pneumonia is occasionally, although rarely, complicated by the occurrence of cerebro spinal meningitis. Immermann and Heller, out of 30 cases of pneumonia, observed this complication 9 times. In these the meningeal inflammation was of the epidemic variety, and hence these observers accounted for the occurrence of this complication as a mere coincidence without any etiological connection.

They are supported in this view by Mende and Githens. Verneuil and Surugue, on the other hand, explained the occurrence of the complication on the ground of the intimate anatomico-physiological relationship existing between the lungs and the membranes covering the cerebro spinal axis. In order to understand their explanation it should be stated that they, in accord with other observers, recognize the occurrence of a meningitis in the course of pneumonia which is not epidemic, but is a simple inflammation. This is the variety of the disease which, according to Huguenin occurs with considerable frequency at Zurich, the field of his labors. In Ziemssen's Cyclopædia of the Practice of Medicine, vol. 12, page 621, he states that the percentage given by Chvostek, at Vienna, 4 out of 220 cases, is lower than that in Zurich. Huguenin has never witnessed epidemic meningitis as a complication of pneumonia.

Nauwerck, in a case of meningeal inflammation which occurred in the course of croupous pneumonia, discovered thrombosis of the pulmonary artery, and hence was led to conclude the complication was the result of emboli. It is doubtless in reference to this discovery of Nauwerck's that Huguenin says: "In two of the cases in which the pneumonia was found in the stage of suppuration, friable thrombi were found in the pulmonary veins; indeed, in one case, even the thrombi were partially broken down by suppuration. The supposition seems warrantable that puriform broken down material gets into the arterial current, is carried by it to the pia, and there sets up purulent inflammation." Jurgensen, in his exhaustive paper on croupous pneumonia in the fifth volume of Ziemssen's work, recognizes the occurrence of this complication, but states that in his experience at Kiel the diagnosis of it was found to be extremely difficult This he attributes to the fact that the meningitis is likely to declare itself only by "a single group of symptoms" He narrates a case in which the complication was shown only by a decided and obstinate rise of temperature which would not yield either to enormous doses of quinine or the repeated resort to the cold bath In contrast to these foregoing Wunderlich, Willich and Sielewicz have noted pneumonia as a complication of cerebro spinal meningitis

The latest contribution to this subject comes from Warsaw and is by PROFESSOR POPOFF In 90 cases of lobar pneumonia he has had 3 complicated by meningitis Two of the 3 died and were examined *post mortem* The pneumonia was in the stage of red and gray hepatization and the meningitis was suppurative, being in one cerebro-spinal and in the other confined to the convexity In all 3 cases the pneumonia was protracted and the meningitis occurred from the twelfth to the fourteenth day, and in all the symptoms due to the complication were marked, such as headache, stiffness of the neck, delirium, etc In the final stages loss of sensibility to pain, inability of the pupils to react to light were noted All set in with chills and headache In all the spleen was enlarged and the urine was found to contain albumen There was also paralysis of the lower extremities for a time in the one which recovered Popoff has collected 34 published cases of this complication, which together with his 3 make 37 in all He finds that 27 were examples of the inflammation limited to the convexity, while in 10 there was also spinal meningitis This fact speaks against the theory of Verneuil and Surugue, since, if the anatomico physiological proximity of the parts was responsible for the complication, the meningitis should in the majority of instances be cerebro spinal and not alone cerebral

Popoff believes also that were Nauwerck's supposition tenable, meningeal inflammation in connection with other affections would be more common, whereas it is well known that emboli find their way more frequently into the substance of the cerebrum than its membranes Renal disease and alcoholism he regards as predisposing factors Popoff attributes the complication to the presence of micro organisms, viz, the pneumonia coccus of Friedlander He assumes that in the stage of resolution these organisms are taken up into the general circulation and deposited in distant parts, there to excite inflammation In support of this explanation he cites the fact that their presence has been demonstrated microscopically in the mininges as well as in other organs Bright's disease and other *cachexiæ* may be of influence in rendering the meninges particularly sensitive to the deleterious influence of the pneumonic poison Popoff distinguishes three types of this disease First, the epidemic variety, which, however, has nothing in common with the pneumonia, second, that in which the meningitis is an accidental complication of the pulmonary affection and is due to embolism or otitis interna, etc, thirdly, the metastatic form, which is caused by the same etiological factor as is the pneumonia He groups his own cases among this last variety

Popoff's conclusions are interesting and, if one be inclined to endorse unreservedly the germ theory, it is satisfactory We are indebted for these facts concerning Popoff's researches to the *Berliner Klinische Wochenschrift*, vol 2, 1886

RECENT PROGRESS IN THE EXTRACTION OF CATARACT

At the meeting of the Académie de Médecine, of Paris, on January 5, M PANAS read an interesting paper on "The Recent Progress in the Operation of Extraction of Cataract" The first factor in the progress that has been made is, he thinks, the introduction of antiseptic methods into eye surgery, especially when the antisepsis has been post-operative So satisfactory have been the results, says M Panas, that surgeons have now been able to return to the flap operation, without iridectomy, reserving the latter for special cases

M Panas gives the following rules for operating 1 Use an antiseptic sure in its action and but slightly irritating, 2 Carry the antiseptic liquid into every recess of the operating field, and for this intra ocular washing should be the rule, 3 Cut a corneal flap as well regulated in form as in size, 4 The toilette of the pupillary field should be as complete as possible, careful attention being paid to every possible source of infection, 5 Before closing the eye operated upon the iris should be made to contract and be completely reduced, 6 Use a strictly antiseptic dressing, and keep the eye at rest for a sufficient time Panas regards the 1-20,000 solution of biniodide of mercury as the best antiseptic that he has yet used for these cases The formula which he uses is 1 litre of distilled water, 5 centigrammes of biniodide of mercury, and 20 grammes of alcohol (90°) The mercury is dissolved in the alcohol, and the solution is then added to the water shaking violently in a large flask, after which it is filtered This solution may be kept for an indefinite time It produces no irritation of the conjunctiva, is well tolerated, save in rare cases, by the cornea, and iris, and may even be injected into the interior of the eye The bichloride is a less powerful antiseptic than the biniodide of mercury, and is much more irritating

Panas does not seem to think the objections raised against the use of cocaine even worthy of mention As regards the incision for the flap, he thinks that one taking in two to three-fifths of the circumference of the cornea sufficient for the extraction of the opacified lens The puncture and counterpuncture are always in the sclero corneal limb With practice the operator will be able to make the corneal flap, in the arc of a circle, by a single stroke of the knife As a rule he avoids including the conjunctiva in the incision, in spite of the advice of von Graefe and Desmarres, since a conjunctival flap is of no use in the reunion of the corneal wound, and it may cause effusion of blood into the anterior chamber, denudation of the sclerotic, etc , which may retard primary union As soon as the operation is finished intraocular lavage is resorted to, after which a few drops of a solution of sulphate of eserine (1–1000) are instilled, while a pomade of eserine and vaseline is introduced into the conjunctival cul de sac By this means the pupil is kept contracted for twenty-four hours, and the iris is reduced To proceed with the dressing, the patient is directed to close the eyes gently, and each is covered with a linen bandage greased with a pomade of benzoate of mercury, which, with its antiseptic value, has the advantage of not irritating the eye in the comparatively large proportion of 1½ to 100 Dry carbolized cotton bandages are then superposed, layer by layer, and the whole is then firmly fixed so as to insure immobility of the wounded eye This dressing is removed every twenty-four hours, guarding against any movement of the eye for three or four days After this a simple bandage may be used to occlude the injured eye for two or three days The patient is usually well within seven days

Besides the shortening of the time of treatment, says Panas, the simplicity of this method is such that he has operated on diabetic and gouty persons, and those in whom acute articular rheumatism or pneumonia have occurred after the operation without cicatrization being retarded In the treatment of senile cataract, he says, he has returned to the flap extraction without iridectomy, iridectomy being reserved for exceptional cases Those who are interested in this subject would do well to read, in connection with the views of M Panas, here presented, the valuable contribution of DR J W THOMPSON, on the "Flap Extraction of Senile Cataract," which appeared in THE JOURNAL of February 20 Panas's paper may be found in the *Bulletin de l'Academie de Medecine*, No 1, 1886

YELLOW FEVER INOCULATION

We learn that Dr Irving A Watson, of Concord, N H , has recently received from DR DOMINGOS FREIRE, of Rio de Janeiro, a report on the inoculation for the prevention of yellow fever He has performed more than 6,000 vaccinations, and not a single person has contracted the disease, although many of them lived in the midst of the epidemic and some acted as nurses for those ill with it Between January and August, 1885 he vaccinated, in Rio de Janeiro while the disease prevailed, 6,051 individuals, not one of whom was sick Of the whole number, native and foreign, 2,282 were less than 20 years old In the district where 3,051 were vaccinated, 166 lived in houses where from one to five fatal cases occurred, and 279 unvaccinated persons died These vaccinations were practiced in the most unhealthy quarters of the city, which epidemics of yellow fever have habitually ravaged

Though no one has yet shown that Dr Freire's figures are false, or his methods erroneous, some of our contemporaries have commenced a crusade against him in which epithets are misused for arguments A Commission of competent medical men, two of whom will be officers of the Government, has been proposed to investigate the matter, and until that Commission reports it would be just as well to let the matter rest *sub judice*

A NEW MEDICAL JOURNAL —We have received the prospectus of a new journal called *The Neurological Review*, to be edited by J S JEWELL, M D , of Chicago, and published by Rand, McNally & Co , monthly, containing not less than 48 pages—with departments for original and selected articles, editorial, and reviews As its name imports, the journal will be devoted to the interests and advancement of the neurological department of medicine Dr Jewell established and edited the well known *Journal of Nervous and Mental Diseases* for several years with unusual ability, and we commend his present enterprise with pleasure, well knowing that whatever he promises he will more than fulfil The first number of the new journal is to appear between the fifteenth of April and the first of May All communications on the subject may be addressed to J S Jewell, M D , No 1239 Wabash Ave , Chicago, Ill

SOCIETY PROCEEDINGS

OBSTETRICAL SOCIETY OF PHILADELPHIA

Stated Meeting, Thursday, February 4th, 1886

THE PRESIDENT, B F BAER, M D, IN THE CHAIR

W H H GITHENS, M D, SECRETARY

DR CHAS MEIGS WILSON reported some

CASES OF LACERATION OF THE CERVIX UTERI WITH UNIQUE SYMPTOMS

The histories of the following cases were brought before the Society in order—*first*, to record what the writer believes to be unique symptoms of the lesion, and *secondly*, to elicit discussion in reference to the reflex nervous symptoms of the lesion, and, if possible, to draw the line of demarcation between them and the nervous phenomena of alienation But a few years ago we were given the doctrine, *ex cathedra*, that lack of contour of the cervix uteri was the principal cause of that train of nervous symptoms of which the histories here cited contain unique examples Prior to this, the clitoris was supposed to be the source of all the trouble And now that spaying has become the fashionable surgical procedure, the ovaries have been given the precedence in the causation of the grave reflex nervous symptoms attendant upon pathological conditions of the pelvic viscera Statistics have pretty well proven that, in a large majority of cases, destruction of the natural contour of the cervix has been the starting point of pelvic distress in a large number of such cases The subinvolution, with the subsequent conditions of prolapsus, hyperæmia, hypergenesis of tissue, ectropion of the cervical mucosa, and the inflammation set up by friction of the everted cervical mucous membrane against the posterior vaginal wall, which frequently occurs in neglected cases of laceration of the cervix, are undoubtedly the primary factors of pelvic irritation in many cases, and it is easy to see how this condition may set up pathological conditions of uterus, Fallopian tubes and ovaries secondarily To say precisely what is to blame is a very difficult matter The following cases are selected from a large number operated upon by Dr E Wilson in private practice, and by the author in the surgical wards of the Philadelphia Lying in Hospital

Case 1 —Mrs McF, æt 32, married, mother of three children, presented herself at the clinic of the Lying-in Charity with the following symptoms For the past year, she had noticed a tumor about the size of a small fœtal head in the right lumbar and the right half of the umbilical region The tumor was perfectly smooth, non nodulated, and freely movable in the abdomen She had had obstinate constipation, a good deal of vesical irritation, at one time had had a sanguineo purulent discharge from the vagina, this had entirely ceased for the last seven months She complained of deep seated, darting pain in the lower part of the abdomen, backache, intense cephalalgia and photophobia Her last child had been delivered fourteen months previously with instruments She had been under the care of a prominent gynecologist who had diagnosticated floating kidney, and recommended extirpation After a careful examination, in which I was aided by several professional friends, the diagnosis previously made was concurred in A careful chemical and microscopal examination of the urine failed to detect any abnormal constituent It was then determined that laparotomy for removal of the kidney, or cutting down upon it and stitching in proper *situ*, would be alike unjustifiable Upon making a more careful examination, including the uterus, the patient was found to have an extensive bilateral laceration of the cervix The contour of the cervix was restored and although the patient still has her floating kidney, all her distressing symptoms have ceased

Case 2 —Mrs S, æt 32, married, mother of two children, pelvis slightly contracted antero posteriorly Both children were delivered alive by forceps This patient was sent me, by her regular attendant, with the diagnosis of cancer of the rectum She suffered greatly from backache and headache, was constipated, passed ribbon stools and had agonizing pain upon defecation She had slight vaginal discharge, and a coffee colored, foul smelling muco purulent discharge from the rectum Rectal examination revealed an ulcerated surface extending apparently for about an inch and a half in length completely around the rectum, about three inches above the anus Small portions of the granular surfaces of the ulcer revealed, under the microscope, no evidence of malignant growth Specular examination of the vagina showed extensive bilateral laceration with acute retroflexion The woman presented no evidence of cachexia The uterus, though closely bound down by adhesions, was finally restored to its proper axis After several weeks the contour of the cervix was reformed Simple astringent applications were made four or five times to the rectal ulcer The patient made a complete recovery, and has had no return of symptoms since the operation

Case 3 —Mrs C, æt 22, mother of one child, with history of tedious instrumental labor This patient suffered from violent ovarian neuralgia, augmented at the catamenial periods She had a profuse leucorrhœa, engorged uterus and enlargement of the right ovary She also suffered at times from suicidal dementia, which was sometimes so violent that she required restraint Her case had been diagnosticated pyo salpinx, and oophorectomy advised Examination revealed an extensive bilateral laceration of the cervix, extending on the left side to the vaginal junction The cervix was restored, with complete cessation of all symptoms Examination six months after the operation failed to find tenderness or enlargement of the right ovary

Case 4 —Mrs S, æt 37, married, mother of five children This patient had been incarcerated in a private asylum for fourteen months, suffering with violent dementia She had the typical appearance of alienation No clear history could be obtained of her symptoms, except that she had distressing pelvic pain and profuse leucorrhœa Examination showed extensive laceration of the cervix Trachelorrhaphy was performed, with immediate amelioration of the symptoms Two months after the operation she was restored to her family completely well A year or more has elapsed since the operation in each of the cases, and the relief afforded has thus far been permanent These cases appear to the author to have had unique symptoms following and consequent upon the lesion, though, doubtless, those with more extended chances of observation have met with cases presenting analogous symptoms

DR JOSEPH PRICE made some remarks upon the effects of cicatricial tissue in the edges and at the apex of the laceration, of the effect of the laceration in inducing local engorgement and hypertrophy, and thus a long series of consequential symptoms He spoke of the value of rest and local treatment for the relief of these symptoms, but the relief so obtained is temporary, it will last but a few months, and sooner or later, after the patient is discharged as cured, the same symptoms recur If the cicatricial tissue is not all removed, and complete union secured throughout the entire thickness of the cervical tissue, the symptoms will return, or even be aggravated by the operation In his experience, conception results after operation in young women

DR HOWARD A KELLY said that he was glad to hear of the good results in Dr Wilson's cases, as a year or more had elapsed He thought cases of laceration of the cervix might be arranged in three classes 1 When the cervix, although lacerated, remains soft and flaccid, there will be no consequent symptoms 2 When cicatricial tissue is developed or ectropion is present, marked reflex symptoms will ensue 3 When there has been natural repair, but with inclusion or formation of hard or scar tissue, there will also be marked reflex symptoms To this latter class belong those cases, with hypertrophied glands and everted lips, of so-called erosion These second and third classes must be relieved by rest and local treatment, and then operated upon to keep them well Complete removal of the hard tissue, and perfect union of the coapted edges, must be secured Failure in either of these points will cause a return of the symptoms

DR BAER said that the symptoms were not due to the laceration, but to its inflammatory consequences To secure a good result, the inflammatory condition must first be subdued, and then the operation of closing the laceration will be in order It may take a long course of treatment to secure this necessary condition, but operation will probably fail to secure the desired relief without the preparatory treatment He had found, in some of these unsuccessful cases, union of the external surfaces only, and in others fistulous tracts between the suture points Cicatricial tissue seems to be sometimes formed after operation when union occurs by granulation Simple laceration without ectropion is very rare, and he would advise repair of the laceration in all cases to prevent future resultant inflammatory conditions It is desirable to have union by first intention to avoid formation of cicatricial tissues and suture-track fistulæ

DR WILSON spoke of the choice of method in preparatory treatment Local treatment once a week will often fail to have a good effect when a week or ten days in bed, with douches of hot water and glycerole of tannin on pledgets of cotton, applied daily, will accomplish rapid relief of the local condition Great care should be exercised in the removal of tissue, as complete closure of the cervical canal may happen He has seen two such cases which were detected at the next menstrual periods after the operation, the passage of a spear-pointed probe gave vent to dark grumous material

DR HOWARD A KELLY exhibited a specimen of

HÆMATOMA OF THE OVARY, WITH ADHERENT FALLOPIAN TUBE

This specimen is an example of a class of cases which stand peculiarly by themselves, cases of aggravated tubal and ovarian disease, on a small scale as compared with ovarian cyst, and yet in which there is enough change in the size and consistency in one or more of the structures of the appendages to afford most satisfactory ground for diagnostic precision under skilled bimanual examination These cases occupy a middle ground between the larger tumors, where disease is so palpable, and those haphazard attempts, the present reproach of gynecological surgery, in which the operation upon appendical structures is undertaken to relieve a *symptom*, and the diagnosis of pathological ovarian or tubal change is made after removal or not at all

This is the right ovary of a patient 21 years of age It is about the size and shape of a large Spanish chestnut I was able to handle it freely by bimanual examination, and determined exactly its size, shape, consistence and relations before operating The indications for operative interference after I had made my diagnosis, were greater than in the case of any large ovarian cyst I have ever seen, and the prospects and result of any form of palliation were futile Almost the whole of this large ovary is filled with a blood clot, soft and jelly like in part and in part firm, fibrous and apparently intimately united to the ovarian stroma This clot is surrounded by a shell of apparently normal ovarian tissue, throughout which are seen a number of follicles and old corpora lutea A remarkable feature is the way in which the fimbriated extremity of the tube is spread out like a a sucker over the surface of the ovary and glued fast by adhesions, so that the line of demarcation between tube and ovary is but faintly indicated From the line of junction numerous vessels course in a radiating manner down over the ovary The left ovary is below normal size, but contains many pea sized black clots

The second specimens which I now exhibit were removed this afternoon The case is an example of the third class, in which the operator has nothing but a symptom to guide him My patient, 35 years of age, suffered from an increasing menorrhagia for fourteen years Lately she has been bleeding half the time She has had recourse to every possible plan of treatment with but slight and temporary relief The only thing I could do was to perform oophorectomy and stop her menstruation One ovary weighs 139 grains, the other 103 grains A beautiful corpus luteum of menstruation, about two and a half weeks old, shows that the hæmorrhages, which retained all along a menstrual periodicity, were in reality menstrual The tubes are free from disease In one ovary a globular pellucid cyst lies between the layers of the broad ligament in close proximity to the fimbriæ, the tubo ovarian ligament being spread out over its surface

Dr Wilson called attention to the fact that in the first specimen the tube had been occluded by a torsion or twist upon itself

Dr Baer remarked that it would be interesting to know the results in Dr Kelly's last case In such a case there is of necessity a cause for the hæmorrhage, there is no apparent diseased condition of ovary or tubes sufficient to account for it Hæmorrhages from the uterus are often associated with vegetations upon its lining surface, but these are not always present He alluded to one case in which hæmorrhage continued to be profuse after the removal of the tubes and ovaries, which had been very much diseased

Dr Price remarked that in this last case the continued hæmorrhage might be the result of body habit, although the original cause might be removed

Dr Harris spoke of a case of fibroid tumor of the uterus with menorrhagia, in which removal of the tubes and ovaries gave immediate relief

Dr Kelly had, eight months ago, removed both ovaries and tubes, and the menorrhagia still continues In the case operated upon to day the curette had been used, but no vegetation had been found A strong tincture of iodine applied thoroughly to the inside of the uterus and vaginal packing would quickly stop the hæmorrhage for the time, but it would soon recur Operation was performed to relieve the symptom hæmorrhage by bringing on the menopause, and not because the ovaries were supposed to be diseased

Dr Joseph Price exhibited specimens from a case of

PYO SALPINX

The tube was as large as the finger and cheesy in consistence, and was easily broken, even by the bite of the hæmostatic forceps The patient was in a typhoid condition, with high evening temperature, emaciation, quick pulse, pain in locomotion There certainly had been leakage of pus before, but two ounces escaped at the time of removal Adhesions were numerous but were cheesy, and broke down readily After the operation there was rapid subsidence of the pulse and temperature, with the other symptoms Free washings of the abdominal cavity through a drainage tube were practiced for a few days There was a clear history of gonorrhœa The other tube and ovary were not enlarged

Dr Beates remarked that in one case upon which he had operated repeated attacks of peritonitis had caused large deposits of flaky lymph in Douglas's cul de-sac These were nicely removed by sponging

Dr. Baer raised the question of the gonorrhœal origin of the salpingitis in Dr Price's case, which was unilateral, while gonorrhœa usually causes both tubes to become diseased

Dr Price stated that Mr Tait's new book reported a gonorrhœal case of unilateral salpingitis Comparing with the male analogue epididymitis, which is usually unilateral, would support the idea of such an origin A free leakage of secretion from the tube, and absence of constriction, may prevent the accumulation of pus on one side

---

CHICAGO MEDICAL SOCIETY

Stated Meeting, February 15th, 1886

The President, C T Parkes, M D , in the Chair

Dr William T Belfield gave a brief outline of

SEVEN CASES OF DIGITAL EXPLORATION OF THE BLADDER IN THE MALE

Case 1 —A patient 58 years old, who had been treated for several years, by various physicians, for cystitis and prostatic enlargement, complete retention had occurred several times A diagnosis of villous tumor of the prostate was made, the nature of the growth being predicated upon the semi gelatinous state which the urine presented after standing for a few minutes—an almost pathognomonic symptom when present Exploration revealed a small villous growth just to the left of the urethral orifice in the bladder, and imbedded in its meshes were found two stones, as large as a pea and a bean respectively, whose existence had not been suspected Patient made a rapid recovery, and was entirely free from his old commplaint three months afterwards

Case 2 —A boy 17 years old had for two years suffered from frequent and painful urination, during which time considerable pus was constantly present in the urine A probable diagnosis of tuberculosis of the urinary tract was made, and was confirmed some time afterward by the discovery of the characteristic bacilli in the urinary pus At the urgent request of the parent the bladder was explored, with negative result Some months afterwards nodular enlargement of the prostate and epididymis were developed Patient's symptoms unimproved by the operation

Case 3 —A man 63 years old, in the last stages of chronic cystitis, was admitted to the County Hospital Had been treated for enlarged prostate No enlargement of this gland could be recognized, but there was found, upon rectal examination, a collection of calculi occupying the exact site of the left seminal vesicle Upon exploration of the bladder it was found that these calculi were contained not in the vesicle, but in a diverticulum of the bladder, where they were completely encysted and covered with mucous membrane This covering was torn and seventeen stones were removed The patient's condition was much improved for two weeks after the operation, but at the end of six weeks he died

Case 4 —A man 38 years old, suffering from all the symptoms of an extremely tight stricture of the deep urethra No stricture could be found Upon exploration of the bladder there was discovered a pedicled cyst attached to the upper orifice of the urethral opening, and completely occluding the urethra like a valve, the tumor appeared to be as large as a small walnut. During an attempt at removal with forceps the cyst collapsed, about half an ounce of clear fluid escaping. The patient recovered rapidly, and has since remained quite free from urinary irregularities. This appears to be the first recorded instance of simple cyst in the male bladder.

Case 5.—A patient 38 years old, admitted to hospital in a typhoid condition, suffering from cysto-pyelitis for which no cause was discovered. Exploration of the bladder showed nothing abnormal. The cystitis and pyelitis subsided completely. When patient was able to leave the hospital, it was discovered that he was suffering from an incipient myelitis.

Case 6.—A man 31 years old, admitted to hospital with violent and fetid cystitis. It was found impossible to pass any instrument over a prostatic obstruction into the bladder; from the rectum the prostate was found irregularly enlarged. Upon exploration of the bladder, a malignant tumor, involving the prostate and a large part of the bladder wall, was discovered. Complete anuria ensued, and death from uræmia on the fourth day. At the autopsy, hydronephrosis of the left kidney, caused by a pipe-stem calculus of the ureter, was discovered.

Case 7.—A man 59 years old was admitted to the hospital for a chronic cystitis of fifteen years' standing, caused by prostatic enlargement. Perineal incision was made for temporary relief. Three weeks later a portion of the obstructing prostate was removed through the perineal wound by the galvano cautery. Complete recovery; the patient, who had for two years been practically unable to urinate except through a catheter, now passed water freely without assistance; the cystitis subsided. Nine months afterwards, acute uræmia and death. At the autopsy, small cirrhotic kidneys were found. This is believed to be the first case recorded in which a considerable portion of the hypertrophied prostate has been deliberately and intentionally removed.

On concluding his paper, Dr. Belfield spoke of a case which came into the hospital in a state of extreme exhaustion, evidencing violent cystitis. Urine containing pus was passed every fifteen minutes with extreme pain. It was impossible to get an instrument into the bladder more than half an inch. The man was half unconscious and could give no history, but by rectal examination it was discovered that the prostate was very much enlarged in the left lobe, the right lobe appearing normal in consistency and size. The doctor thought this almost a proof that in a man of this age, 31, the seeds of tuberculous disease were present. The bladder was opened and the finger inserted in the usual way, discovering a malignant growth covering an inch and a half of the left wall of the bladder. After the operation the patient passed half an ounce of urine, but died in three days from uræmia. The bladder and kidneys were secured and found to be the seat of extensive hyperinosis, caused by a calculus. Another case was that of an emaciated French Canadian who had had trouble for eighteen years, and had depended entirely for urination upon the catheter for two years. The usual perineal incision was made, and a portion of the prostate removed. The operation was successful and the man was able to do without the catheter, although Dr. Belfield advised its use once a day. In June he had a slight attack of cystitis, due to the fact that he had persisted in ignoring the advice in regard to the use of the catheter. About the 10th of September he was taken with uræmic convulsions, and died on the 18th. The last few days the urine became cloudy again. The bladder and kidneys were secured, and a channel found in the prostate large enough to admit the forefinger. Dr. Belfield thought it would have been better to have cut down from above in the hope of relieving the prostatic tumor.

DR. E. ANDREWS suggested to the members that this subject was more important than has formerly been supposed. The former examinations made in these cases were very imperfect, and though the finger used occasionally to be put in the bladder it was not dreamed that the whole circumference of it could be reached. He thought it should be impressed upon the members of the profession that the bladder can and ought to be explored.

THE PRESIDENT thought this procedure for diseases of the bladder so new that it might be called novel, and it seemed singular that at so late a day the bladder should be explored in this way, when surgeons have so long known that the bladder could be opened in many ways without injury to the patient. He thought the profession greatly indebted to Dr. Belfield for his remarks.

DR. W. M. AXFORD thought an incision in the perineum might facilitate a cure in cases of fistula, which at present are very difficult to cure, but did not know that it had ever been tried. We do know that such fistulæ are very difficult to cure, probably because the urine continually runs over them. The procedure is practically harmless and may effect a cure.

DR. W. T. BELFIELD said, in conclusion, that this procedure of inserting a drainage tube through the perineal wound for curing fistula of the urethra is mentioned in Harris's book, and seems to work with entire success. There was one point upon which he congratulated himself, viz., the discovery of cyst of the bladder. So far as he knew nothing of the kind had been recorded in either the pathological or clinical literature of the bladder. The misery that it can cause is illustrated in the case under discussion, and from its nature it offers every hope of a cure.

DR. W. L. AXFORD read a paper on

NOTES ON GENITO URINARY SURGERY,

in which he said that he believed gleet is due to a stricture of the urethra, and can be cured by curing the stricture. He believed that dilatation cured a stricture by exciting inflammation at the seat of the stricture, and thus causing the absorption of the exudate. In the treatment of strictures he believed that perineal section is best in strictures which are deep seated, narrow, or unyielding, or complicated by fistula or urinary infiltration; internal urethrotomy in all strictures of the meatus or fossa navicularis, for they will not stretch. For other strictures he would advise, as the case demanded, dilatation, divulsion, or internal urethrotomy If the stricture is resilent, divulsion or internal urethrotomy, preferably the latter He believed the dull pain in the back, and at times in the head, during the later stages of gonorrhœa to be due to urethral reflexes Cure the gonorrhœa or stricture and these disappear

He cited cases in which severe cephalalgia and skin diseases had been cured by curing strictures by internal urethrotomy Also, cases in which dysuria and vesical discomfort had been allayed by slitting the meatus In female urinary troubles, after excluding uterine disease, he had given relief by digital dilatation of the urethra

Dr E Andrews referred to the point whether there is any danger or not in urethrotomy European statistics show a considerable amount of danger in operations for stricture He did not know the reason for mortality in Europe, for he thought it the general experience in Chicago that men don't die of these operations Long ago he had left off keeping count of the cases he had operated on, and could not recall an instance in his own practice or that of any one else in this city in which the patient died in consequence of the operation for stricture As to the question of divulsion, or cutting, he had performed the two operations indiscriminately, sometimes both on the same patient He thought divulsion and cutting produce precisely the same result Some strictures will stretch out under the divulsor and go back again, and cutting is better for these cases, but neither appears to be dangerous He had found divulsors from New York instrument makers repeatedly breaking down under strong strictures Otis's instrument he thought exceedingly strong, but even that had failed in one instance He expressed the belief that divulsion, thoroughly carried out, is as safe as cutting

Dr F E Waxham referred to a unique case coming under his care of stricture in a child aged four years He was convinced, however, that stricture is very rare among children This was the only case that had come under his observation Otis alludes to two causes—masturbation and gonorrhœa In this case he found no history of gonorrhœa, and the mother denied the practice of masturbation The child was put under the influence of ether, the stricture was so closed that he could only enter the bladder by means of a very fine bougie, this was followed by a larger one, this by a small catheter, and this by a steel sound, and the child was then able to pass the urine without difficulty Before dilatation the child would undergo the greatest suffering every time he passed water, would scream and strain for several minutes, and oftentimes strain so severely as to cause evacuation of the bowels After the first dilatation the child did nicely for a week and then was as bad as ever, the second dilatation was three weeks ago, and there has been no further trouble

Dr A B Strong asked if the cure was permanent, after cutting unless constantly followed up with the catheter He wished to know if there is anything better than simple dilatation Cutting and divulsion are more rapid, but he thought gradual dilatation offered as good and permanent results

Dr W T Belfield suggested two points in Dr Axford's paper that required notice, the value and the safety of cutting He thought it absolutely imperative that we limit our cutting operations strictly to the pendulous urethra This was not merely a theoretical and anatomical consideration, but a practical one He thought Dr Axford in speaking of the three methods, stretching, divulsion and cutting, omitted one of the most importance, viz , the use of a constant electric current Although this had not received a great deal of attention from the profession he thought anybody who tried it would never give it up It is said to produce the most permanent results, and is convenient and easy He had tried it in his own practice, once in the hospital where he had the privilege of cutting, but tried the battery out of curiosity and found it worked nicely, and again in private practice where it was extremely important to the patient that no perineal section should be done As to stretching the female urethra with the fingers, he thought it dangerous When house surgeon in the County Hospital he had seen a woman die of peritonitis when that was done He thought the best instrument for this purpose to be Stein's dilator, which has a continous dilatation

Dr W L Axford said, in conclusion, that dilatation always has to be followed out by the occasional passage of the sound for an indefinite period of time; all the patient's life If the stricture is divided clear through Dr Otis claims that a perfect cure will be made and no after treatment will be necessary Dr Axford thought that Dr Otis, although an extremist on this subject, is about right As to cutting in the membranous urethra, he did not think anyone would do that He had never had experience with the galvanic current, had heard it recommended and also discountenanced In dilatation of the female urethra he had always used his fingers and succeeded first rate Would always prefer to use his own hand, as no instrument equals the human hand

(*To be concluded*)

DOMESTIC CORRESPONDENCE

BRANCHES OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor of the Journal

Dear Sir —I have read with much interest "Branch's" letter in The Journal of February 6th, and agree with him that the matter ought to be taken up at the coming meeting in St Louis Within recent years the Association has taken two important steps—the establishment of The Journal and the admission of "Members by Application" These have materially extended its influence and increased its membership

The numerical relation between the regular profession in the United States and the Association is still small, but even if an increase exceeded the most sanguine expectations a scattered membership of many thousands would not be so powerful as one smaller but disciplined and united What is wanted is organization, a system by which the profession can express itself as a unit upon vital questions, and through which the greatest possible benefit will accrue to individual members The British Medical Association is thoroughly organized by numerous branches, yet the area of territory in which this system has been found so successful is less than that of many States of the Union In this vast country members of the American Association are scattered North and South, East and West, the only method of reunion is an annual meeting, which takes many practitioners a journey of 2000 miles to attend, and an expenditure in time of two weeks During the interval between these assemblies the Association is practically non-existent, it is difficult to obtain even a collective expression of opinion, and as a factor in politics its influence cannot be exerted, owing to the want of proper representation

It will be impossible for regular medicine ever to attain its rightful position in America without some system whereby its sentiments can be voiced, and this should be the National Association, organized by its branches, in every State and Territory, represented and governed by its council, and kept in constant communication through its JOURNAL The methods by which this is attainable must be adopted at a general meeting of the Association, but it will be profitable to discuss the matter beforehand, so that they who undertake its inception may have the benefit of previous deliberation Meanwhile, it is well to deal with the objections which may be urged when it is proposed to interfere with existing organizations

The "two reasons" which "Branch" puts forward in regard to State Societies are really the principal obstacles to encounter, namely status and finance Of these the first is least important There would be no "dependency" except in theory The Society which organized with similar objects and adopted the "Code of Ethics" of the Association for its guidance is already in close affiliation, otherwise its autonomy is complete In its own section it should be supreme, and it would remain the centre to which the local societies focus The subject of finance is more important and must be carefully considered It is not too sweeping a statement that no State Society is numerically as strong as the regular profession in that State would entitle it to be Its income is small and modest balances in the treasury are the rule The principal expense is the annual volume of Transactions Whether this publication is desirable is a question No doubt much of the matter might be "profitably dispensed" with and the "very bad" papers omitted, but it is well to bear in mind that some of these are reports from various sections and must necessarily be printed They, however, serve a useful purpose by acting as an incentive to better work, and tending largely to keep alive an interest in the Society and its annual assembly THE JOURNAL of the Association could not undertake to publish more than the minutes of a meeting, yet any scheme which proposes to abolish the publication of this matter will probably be received with disfavor, and in my opinion may be harmful in its action With local or County Societies the case is different They do not publish their transactions, and the actual running expenses are comparatively trivial, so that their amalgamation would present fewer difficulties

It is open to consideration which should be adopted, either to make each State Society a Branch of the Association, or to organize small Branches and leave the State Societies as now constituted As a commencement the latter appears to be the most feasible project and likely to afford a large measure of success Taking the expense *per capita* "Branch" says that "the number of members of State Societies who cannot afford to pay two sets of dues is extremely limited " This is very true, and with it comes a question of economy A large number of physicians belong to a local society, the State organization, and the Association as well, so that they pay three sets of dues If, therefore, a comprehensive scheme be devised which shall organize the profession under one common head, a saving can certainly be effected

I trust that the matter will be fully discussed and some measure adopted which will enable a Republic of Medicine to rise and flourish in these United States Yours truly,

JAMES H PARKINSON, L R C S

Sacramento, California

TO THE EDITOR OF THE JOURNAL

Dear Sir —In your issue of February 6th is an item of correspondence on "Branches of the American Medical Association " I am sorry that I cannot altogether agree with the conclusions of your correspondent as to the propriety or wisdom of the proposed "Branches " Let us examine the question with a little care "Branch" proposes that we shall, in this country, adopt the method of the British Medical Association to perfect our own organization Their method, as he sets forth clearly and distinctly, consists in the formation of Branches under regulations of the General Council of the British Medical Association, in which each Council in each Branch has a single voice, and that "any number of members, not being less than twenty, may form themselves into a Branch of the Association, subject to such Branch being recognized by the Council Each Branch shall be free to govern itself as its members shall see fit, but no Branch law shall be valid which, in the opinion of the Council, may contravene any fundamental law of the Association Each Branch shall pay its own expenses, and no Branch shall be deemed for any purpose the agent of the Association, or have power to incur any obligation in its behalf "

There are thirty-four such Branches, it is stated, in the British Medical Association It occurs to me in the consideration of this question that, while the so-called Branch plan may be a very desirable one for Great Britain, it is not adapted to the customs of this country, and the "plan" will not be popular, or meet the wishes of a majority of the profession The object of the proposed change, if I understand your correspondent correctly, is to increase the power and membership of the American Medical Association It seems to me that very desirable object will be much better attained, with less friction, if we simply open the doors of the Association so that its members shall include the members of affiliated State Medical Societies who shall have inscribed their names on the register, and certified their adherence to the regulations of the Association for the government of its members in professional life. The adoption of such a rule would at once make every member, in good standing, of a State Medical Society in affiliation with the American Medical Association sending delegates to its annual meetings, a member of the American Medical Association. The rule might further provide that any member failing to pay his dues for any year would thereby become indefinitely suspended from membership in the Association. This plan, it seems to me, is much simpler than the one proposed by your correspondent. It utilizes already existing organizations, and does not change the present plan of organization, which is what I may designate, as contra distinguished from the British plan, the American plan, and therefore, in my opinion, decidedly preferable for use here, to any imported from Europe.

It is not possible for every member of a State Medical Society to attend the meetings of the Association, but by their being permanent members of the Association they will be entitled to the receipt of THE JOURNAL, and then, as now, in the election of delegates to attend the business meetings of the Association—they alone having power to vote—they will be fully represented. So, then, it appears, as a matter of fact, the State Medical Societies, in affiliation with the American Medical Association, are already "Branches" in effect, and it only remains to open the doors of membership to all members of the respective Branches, *i. e.*, State Societies in good standing. The autonomy of the "Branch" is nominal in England, in our country it is real, and in accordance with our political system, which medical men, as patriots, ought to uphold rather than decry.

Therefore, while I favor the widest possible basis of membership for our general Association, I should oppose the supplanting of our State Societies by any Branch of whatever degree, and in fact there is no need, for as already pointed out, the present State organizations can not only strengthen the general Association by encouraging large membership therein, but if the American Medical Association bases the claim to membership on the applicant's standing in his own State Association, that basis will also serve as an element of strength to the State Society, thus proving the wisdom of the old moral which we adopt as our political maxim, that "in union there is strength." Very respectfully yours,

JOHN B. HAMILTON, M.D.

Washington, February 10, 1886.

TO THE EDITOR OF THE JOURNAL:

Dear Sir:—I have been much interested in the letter which dealt with the subject of "Branches" in your issue of February 6, page 163. No one can take exception to the spirit of that letter, though one may differ when it comes to the details and their execution. The formation of such Branches, in my opinion, should proceed somewhat differently from the method suggested by "Branch."

In the first place the American Medical Association should be divided into a *governing body* and a *working body*. The latter could be composed, as it is now, of members of the regular profession, who have attended in the capacity of delegates to this part of the organization, its Sections and of "Members by Application." The former should be composed of *delegates only* of State and Territorial Branches, who should be chosen by these bodies under rules made by the American Medical Association, somewhat like this:

1. The Branches of the American Medical Association shall consist of the legally recognized State or Territorial medical organizations.

2. The State or Territorial Branches of the American Medical Association shall be composed of two parts, a governing body and a working body. The former shall be composed of delegates, one for every subordinate society, of all medical organizations, who recognize the authority and subscribe to the constitution and By-laws of the State or Territorial Branch of the American Medical Association.

3. The working body shall consist of all regular physicians, who are elected to membership under the rules of the Branch, not conflicting with those of the American Medical Association. All laws and all matters tending to maintain and enhance the interests of the American Medical Association, its Branches and their members, shall emanate from the governing bodies, to be known as the Council of the American Medical Association and the Council———Branch of the A. M. A. respectively, with this proviso, that everything suggested by such Councils must receive a ("two-thirds," or "three fourths"?) vote of the whole Association in annual meeting assembled to legalize it. And, further, no rule or motion shall be adopted by a Branch, or its component parts, which conflicts with the already existing rules of the higher organization.

4. The Council of the American Medical Association shall consist of one delegate for every (ten or twenty?) members of the State and Territorial Branches. Said delegates must be members of the Council of their respective State or Territorial Branches. Provided, however, that no person shall be eligible to the Council of the State or Territorial Branch, who has not submitted a paper, in some Branch of the science of medicine, which has been accepted for publication by his society. And provided further, that no person be eligible to membership in the Council of the American Medical Association who has not submitted a paper upon some subject connected with the science and art of medicine, which has been accepted for publication by the State or Territorial Branch of the American Medical Association of which he is a member.

5. The members of the Councils of the American Medical Association and its Branches shall be known as "Fellows" of the American Medical Association, and as "Fellows" of the———Branch of the A. M. A. respectively. And they shall retain this title as long as they are in good standing in their society and

State or Territorial Branch. All officers of the Branches of the States and Territories, as well as those of the American Medical Association shall during their service be *ex officio* members of the Councils of their respective societies.

Such suggestions amended as wisdom shall dictate, would be followed by many benefits, the formation of local societies, both in cities and counties would be stimulated, the State organizations would grow strong, *pari passu* with the multiplication of local societies, and the whole profession of the United States would have the novel experience of demonstrating for itself, that "in union is strength." But this beneficial reaction would not only appear in the political and social relations of the medical profession but also in its scientific aspect. For the scheme offers advancement and position only to those who distinguish themselves by their work in the field of medical science and practice.

A dependency of the State and Territorial Societies upon the American Medical Association would be established only in so far as the Branches need the *strong arm* of *union*, whilst in all other matters they would be as unmolested as ever. For really a moral dependency exists now, as was demonstrated by the action of the American Medical Association towards the New York State Medical Society, and towards a member from Nebraska in late years, who was prevented from taking his seat in the Association on account of non-payment of dues in his State Society. Why not call into life the strength of "legal dependency," when its weaker brother, the "ethical submission," existed long ago? A relationship which would supplant the restriction of the few in wrong, by the protection of the many in right would certainly be a long step forwards.

Another, and by no means small factor in such a scheme, would be the strength and therefore usefulness, which the JOURNAL OF THE ASSOCIATION would receive. "Branch" says: "It could scarcely be supposed that all the papers could be published in one journal." I cannot understand why such a supposition should not be entertained. If the membership of the American Medical Association could be doubled, why should not THE JOURNAL OF THE ASSOCIATION be enlarged one half its present size? A journal of the dimensions of the *London Lancet* could easily publish, in its fifty-two yearly numbers, all the papers submitted at the State Society meetings and and at the annual meeting of the Association—especially if a little more of the "survival of the fittest" were indulged in, which would be as beneficial to medical literature as it is to nature. The present tendency in medical journalism is evidently in the direction of the representation of specialties, thus limiting the need of general journals more and more. These will find their usefulness only in the publication of *news*, and of matters of general interest to the profession, and these things the JOURNAL OF THE ASSOCIATION could certainly furnish, and fitly so, for every physician in the United States. And here the suggestion of "Branch," somewhat modified, would apply. Members could publish their papers in journals devoted to the specialty of which they treat, and if these journals did not accept them it can most generally be surmised that the emanation was not worth printer's ink. It is eminently correct that many papers, instead of making the costly yearly transactions more costly still, had better find an early grave in the waste basket of the editorial sanctum.

It will be seen that my scheme differs from that of "Branch" in one particular materially. He says of the British Association: "Any number of members, not being less than twenty, may form themselves into a Branch of the Association." This is already true of the American Medical Association, for it recognizes delegates from any regular Medical Society in the States and Territories, and in my opinion this is the very weakest point in its organization. By this action it sustains the Local Societies at the expense of the State Societies, and these in their turn pay the Association with the same coin, with this difference, however, that the Association lavishes its privileges upon independent local societies whilst the State Society, deprived of the strength of these local societies, sends a weaker delegation to the Association's meetings. The proviso that such bodies must be recognized by their State Societies goes for naught, we have one of these societies in my State, it does not affiliate with the State Society, and yet every member thereof would be entitled to recognition by the State Society and the American Medical Association. They ignore the former and acknowledge the latter, and, permit me to say it, the Association meets only once a year and a good ways off from them, so they are safe.

The *body* of the medical profession of the United States—the American Medical Association—should not be connected with its *fingers* only (the local societies) as it is now, but should interpose the strong *arms*, as represented by the State and Territorial Societies, thus making the fingers more useful, the body more powerful, and the whole more harmonious. This is evidently the object of "Branch," it is the hope of

STATE SOCIETY.

TO THE EDITOR OF THE JOURNAL:

Dear Sir:—In regard to the communication signed "Branch," which appeared in THE JOURNAL of February 6, I submit the following. It seems that the British Medical Association is formed or made up of societies which are known as Branches, and that a man who becomes a member of a Branch is at once a member of the Association, and that a part or the whole of the membership fees and dues go to the Association. The American Medical Association is made up of permanent members and delegates from State, District, County and Local Societies. Until recently, in order to become a member of the Association, a physician had first to be delegated from his Local or State Society, and be thus registered on the books of the secretary. Then he was a permanent member as long as he stood well in his Local and State Societies and paid the annual dues to the treasurer of the Association. Now, any man in good standing in his Local or State Society can become a permanent member of the Association by bringing proof of such standing, paying his dues and signing the Constitution. In the British Medical Association a physician becomes a member as soon as he joins a Branch.

In the American Medical it is different. Membership in a Local or State Society in affiliation with the American Medical Association only *qualifies* the physician to become a member of the Association. With this last exception, and the dividing the fees and dues paid into the Branch Societies, with the Association, the laws governing in the American Medical are very similar to those governing in the British Association, and I can see no other object in making the changes suggested than that of increasing our membership and strengthening or replenishing our treasury, at the sacrifice of our State Societies, which have done good work in standing as the only gates through which entrance to the Association could possibly be effected, and it occurs to me that the moment they are removed we will let down the bars to hordes of crooks and charlatans, whose crookedness shuts them out of Societies at home where they are best known. Once the Association determines to remove such safeguards, the Code will become a thing of the past and the Association the resort of thousands who disgrace the name of doctor. Fearing that such would be the effect of the changes suggested by "Branch," I must beg to record myself as against the paper in its present shape, though in doing so I ask that you will not class me among the opponents to any change which will redound to the dignity and prosperity of the Association.

Very truly yours,

J. M. Keller.

Hot Springs, Ark., February 9, 1886.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Laparotomy in the Treatment of Penetrating Wounds and Visceral Injuries of the Abdomen.

At the last meeting of the New York County Medical Association, Professor Frederic S. Dennis read probably the most elaborate paper that has yet been prepared on *Laparotomy in the Treatment of Penetrating Wounds and Visceral Injuries of the Abdomen*, and it was most richly illustrated by pathological specimens of great variety from a number of the cases referred to in it. The conclusions at which he arrived after a full consideration of the subject were stated as follows:

First. That penetrating stab wounds of the abdomen are less fatal than penetrating gunshot wounds, but that the former are fatal in too great numbers to allow the surgeon to be content with the older methods of treatment.

Second. That if the stab wound has injured the intestine or any abdominal organ, laparotomy is indicated. It may be indicated also in cases where the gut is not perforated, but where it may have become twisted as a result of the stab wound.

Third. That in a penetrating stab wound in which doubt exists, the diagnosis should be made certain at once, in order to pursue a proper line of treatment.

Fourth. That laparotomy offers no additional danger to the patient, if properly performed with the strictest antiseptic precautions.

Fifth. That while the number of cases in which there was an exploratory laparotomy made in stab-wounds of the abdomen affords insufficient data upon which to establish any fixed rule of practice, the same principle which is recognized in the performance of laparotomy for gunshot wounds of the abdomen is also applicable to penetrating stab wounds.

Sixth. That the enlargement of the original wound for an examination of the peritoneal cavity will not enable the surgeon to exclude in all cases fæcal extravasation, perforation, volvulus and hæmorrhage. These may all exist, and yet no evidence of their presence be manifested upon inspection through a small opening.

Seventh. Neither the size, shape, character and velocity of the bullet, the attitude of the patient at the time, nor the kind of weapon used to produce a stab wound, seem to Dr. Dennis to influence the question of laparotomy.

Eighth. It is possible to have a fatal hæmorrhage from the large venous trunks in the abdomen, and this hæmorrhage not be discovered until the cavity is about to be closed.

Ninth. That the sutures, if properly applied, will close the perforation in every case, no matter how lacerated the wounds are, or the sutures will close the wound in case of resection of the gut, so that no leakage will occur if water is forced through the sutured interstices.

Tenth. The success of laparotomy is to be attained when every arrangement is complete and perfect.

Dr. Dennis paid a tribute to the remarkable foresight of the late Professor Gross, of Philadelphia, whose prophetic utterances of nearly half a century ago in regard to this subject he quoted, and said that the credit of this great achievement will be found to be due to the influence and teaching of Gross, Marion Sims, and Parkes, of Chicago, while it remained for Dr. W. T. Bull, of New York, to make the practical application of the knowledge acquired from Dr. Parkes's experiments to a higher use. It was indeed, he said, from a cursory view of these chronological facts that laparotomy in penetrating abdominal wounds and visceral injuries was conceived, developed and perfected in America.

Among the cases mentioned in the paper were a considerable number which had been treated by Dr. Dennis himself. While treating of penetrating stab-wounds he reported two cases of great interest, in both of which he was enabled to present the patients, restored to health, to the members of the Association, who had an opportunity of inspecting the cicatrices left. The first was that of a young man 22 years of age, who was admitted to St. Vincent's Hospital in November, 1885, suffering from two abdominal wounds inflicted with a knife. The intestines, which were perforated, protruded, and there was fæcal extravasation, but not into the peritoneal cavity. The wounded intestine was sewed up with catgut sutures, and after a careful examination had been made for other wounds in it, returned to the cavity, and the external wound closed He remarked, in connection with this case, that the operation of exploratory laparotomy was not called for in this instance, because the intestines protruded, and could be drawn out and sufficiently examined without such an operation, and that a concealed wound would have been much more dangerous

The other case was that of a negro 57 years of age, who was admitted to his wards in St Vincent's Hospital December 20, 1885 He had been stabbed in the umbilical region to the left of the median line, and from the wound, which was one and a half inches in length, protruded a finger-shaped piece of omentum The latter was tightly compressed by the edges of the wound, and was afterwards removed by Dr Dennis Antiseptic gauze was immediately placed over the parts, and three hours after the accident laparotomy was performed under strict antiseptic precautions A vertical incision was first made in the median line, and then a second one, diagonally, which joined the wound to this The viscera were thoroughly examined from the stomach to the inguinal flexure of the colon The small intestines were turned completely out of the body, and omentum and mesentery carefully inspected, but no injuries were found He remarked, by way of comment, that it might be objected that laparotomy was not necessary in this case, but in answer to this he would simply call attention to the fact that this was not known at the time If the intestines *had* been wounded, and laparotomy had *not* been performed, the patient would undoubtedly have died The laparotomy was called for, therefore, in order to find out what the actual condition of affairs was This, he believed, was the first laparotomy which had been made in the case of a stab wound where it was not *known* that the intestines were wounded In another case of the same kind, however, he would now recommend that the wound itself should be enlarged sufficiently to make an examination of the intestines before performing laparotomy proper, as this procedure was a little more conservative The operation in this instance, he wished it to be understood, had not been sudden and unpremeditated, but was the result of much study and experience in connection with other similar cases

In speaking of gunshot wounds he also reported in detail two cases of his own, in both of which laparotomy was performed The first was that of a young man, 23 years of age, who was admitted to the 99th Street Reception Hospital January 2, 1886, suffering from a penetrating wound of the abdomen caused by a 32 calibre pistol ball Severe shock was present, but laparotomy was performed, when it was found that there was the most profuse hæmorrhage in the cavity The examination showed that the principal source of this was the veins in the transverse fissure of the liver There was no wound of the intestines On account of the extreme exhaustion of the patient, twelve ounces of a saline solution were injected into the radial artery This was followed by marked benefit, and the same thing was therefore repeated every four hours, the canula being in the meanwhile retained in the artery At the end of forty eight hours, however, the patient died, and at the autopsy the bullet was found imbedded in the right lobe of the liver, the wound being necessarily a mortal one, on account of the irreparable injury to large blood vessels

The second patient, aged 22, was admitted to the same hospital January 10, 1886, also suffering from a penetrating abdominal wound inflicted by a 32 calibre pistol He had marked shock, and laparotomy was resorted to by Dr Dennis There was fæcal extravasation, and seven openings in the intestine, with one in the mesentery, were found The hæmorrhage was so enormous that, on account of the alarming condition of the patient, the operation had to be abandoned before its completion, and death ensued in forty-eight hours after the injury At the autopsy the cavity of the abdomen was found completely filled with blood, but the sutures which had been made in the intestines rendered them perfectly water-tight

He remarked, in connection with the frightful and uncontrollable hæmorrhage met with in these two cases, that at present the great desideratum in laparotomy for penetrating wounds was some means of arresting hæmorrhage from such large vessels as the vena cava and the iliac and portal veins, and it had occurred to him that this might possibly be accomplished by constriction of the thighs and the waist for a sufficient time to enable the surgeon to secure the bleeding trunks When this point was accomplished, he believed that laparotomy as an operation would meet with the most brilliant success In one case which he referred to, in which laparotomy was not performed, no less than ten perforations of the intestine were found at the autopsy, and the failure to resort to the operation therefore deprived the patient of the only chance of recovery that he had In this instance the existence of perforation was not suspected by the surgeon in charge, so that it forcibly illustrated the advisability of exploratory laparotomy even in comparatively favorable cases

Besides penetrating stab and gunshot wounds of the abdomen, Dr Dennis mentioned a third indication, viz rupture of the intestine A number of cases, illustrated with specimens, were related In two the patients were run over, and in the others injuries of various sorts were received As far as he had been able to discern, only two cases of laparotomy for rupture of the intestine from traumatism had ever been reported In speaking of this class of cases, he referred particularly to emphysema of the tissues and loss of hepatic flatness on percussion as indications of perforation Collapse, he said, was the only constant symptom, but it was not pathognomonic The rupture was always in the small intestine, and the contraction of the muscular fibres usually prevented fæcal extravasation The performance of laparotomy in these cases enlarged the domain of abdominal surgery, although no successful result in it had as yet been reported

In treating of the signs of visceral perforation in general he said, in regard to the matter of shock, that the persistency of the shock was of more significance than its severity, and when it was persistent, it afforded a strong link in the chain of evidence The shock, however, he said, was more apparent than real, being due rather to the sympathetic than to the cerebro spinal system, as was also the case in strangulated hernia He thought its presence should not deter the surgeon from performing laparotomy, and in his own cases he had found that the collapse improved after the opening of the abdomen Shock, however, affords no direct evidence of perforation, and a number of cases were on record in which, although perforation had actually occurred, there was little or no shock present, and death occurred almost without warning

In the discussion which followed, Dr Joseph D Bryant, who opened the recent debate on the same subject in the Surgical Section of the New York Academy of Medicine, called attention to the necessity of discriminating sharply between the two forms of the operation, viz exploratory laparotomy and laparotomy in its entirety The performance of the former he advocated much more frequently than was now the case, believing, as he did, that when done under proper conditions it exposed the patient to no unusual danger The performance of the latter, however, was a much more serious procedure, involving no little skill, patience and expenditure of time, and requiring the most favorable conditions for its success In this connection, he remarked that he would not consider a case of laparotomy in its entirety one in which there were found no injuries of the intestines or other viscera In regard to shock, he agreed with Dr Dennis that it was perfectly justifiable to perform exploratory laparotomy whether it was present or not Whether the exploratory incision was to be made in the median line or not depended on the direction of the violence producing the wound If this was towards the median line, the incision was to be made in the latter, but if the direction was from the median line, it was to be made at the seat of the external wound He spoke also of the very great importance of hæmorrhage, and said that it was absolutely necessary, in performing laparotomy in its entirety, that every bleeding point should be satisfactorily secured Not infrequently very slight oozing became changed to profuse hæmorrhage as soon as the abdominal contents were returned to their places, and the cavity was closed up Experiments which he had made on dogs (shooting them in the abdomen, and then performing laparotomy), had further convinced him of the extreme importance of this element in gunshot wounds of the abdominal cavity

Dr E G Janeway said that the absence of hepatic dulness was a good general guide as to the existence of perforation of the intestines, but there were a certain number of cases which simulated this condition Thus, in a case of typhoid fever under his observation, in which, on account of this symptom, perforation was supposed to have taken place, it was found at the autopsy that the resonance over the hepatic region was not due to perforation, but to the tilting of the liver

Dr H M Briggs also related a case which went to show that loss of hepatic dulness was not an infallible sign of perforation It was one of peritonitis, and the absence of liver dulness being detected, it was naturally supposed that perforation had occurred At the autopsy, however, it was found that this was not the case, but that the intestines had become forced between the liver and the abdominal walls

Dr J W S Gouley said that he believed that the views expressed this evening were sound, and that laparotomy was justifiable when we had reason to believe that the hollow viscera had been injured At the same time, numerous instances were on record in which recovery had taken place under these conditions, and as illustrations he related two cases which had come under his observation during the late war In one instance the patient had a bayonet wound completely through the body, and in the other a pistol shot also passed completely through the body In the latter case the right lobe of the liver, as well as the lower lobe of the right lung, was injured, and bile flowed freely out of both openings with the pus Still, he did not hesitate to say that if he were to deal with such cases to day, he should prepare himself to open the abdomen An interesting case, with recovery, which had been under his care during the war, was also related by the President, Dr Leale

After this instructive scientific session the members adjourned to the library of the State Association, where they enjoyed a pleasant collation and social reunion, which included the passing around of a festal "loving cup," filled with a most delectable concoction, the offering of Dr Flint P B P

TARTAR EMETIC VACCINATION

To THE EDITOR OF THE JOURNAL

Dear Sir —The articles of Drs Woodworth and Ziegler bring the following facts to my recollection As is well known, Prince Bismarck allowed, during the Franco-Prussian war, American surgeons to enter the services of his Government, and appointed the late Dr Krackowitzer and Dr Abraham Jacobi, from New York, a Board of Application, to certify diplomas and the respective ability of applicants, who were requested to send in a certificate of a regular medical practitioner in good standing, as to their previous lives, practice, etc Having been accepted by the Board, I embarked on the Anchor line steamship "Europe" to Glasgow, and from there to the seat of war After our services ended the well-known Dr Knapp, of Berlin, was entrusted by his Government with furnishing us the funds for our return travel, and by-the way, it was almost as hard to get out of the service as to get in, on account of "red tape"

Thinking that I could save some of the money, I started for Hamburg and looked around for a ship, where I could make my way as surgeon I succeeded in finding the "Palmerston," bound for New York We had 700 emigrants on board, no cabin passengers *except me* The steerage was good and comfortable, food and water through all our long tedious journey excellent On the seventh day out I was notified that an old man was sick, and on examining him I found that he had small pox I separated him and the family, two grown daughters, from the rest of the passengers and began to disinfect the ship thoroughly with carbolic acid, sulphur and juniper berries, the latter more for the smell than anything else The infected man was 67 years old, and died within three days The daughters had small pox rather severely, but survived His clothes and everything pertaining to them were thrown overboard, the girls' clothing was steamed in a special oven These three cases were the only ones which occurred on our ship When the passengers heard of it there was quite a panic among them, but after I told them that all possible precautions would be taken by me to prevent the spread of the disease, they quieted down I began now to inspect every passenger, including the crew, and found that about one hundred of the passengers were not vaccinated There was no virus on board, and recollecting of having read somewhere about the identity of the pustules of tartar emetic and small pox pustules, I resolved to try a few inoculations with tartar emetic

I inoculated myself first, and having been re vaccinated when fourteen years old, I could not find any difference between the two From myself I inoculated some babies, and saw that the course was nearly identical with true vaccination, the pustules could not be distinguished from real vaccination pustules It must be remembered that during our services in the Prussian army we had an extended opportunity to see small pox (especially among the French), so that I am well aware of what I write I inoculated all the passengers and had the satisfaction that every vaccination took Our journey, on account of contrary winds, was a tedious and long one, lasting sixty days, though time passed swiftly enough for me When we landed in New York I reported to the Assistant Health Officer of the port, the late Dr Mather, of Albany, the incumbent, Dr Cochran, then being sick We got, without any trouble, a permit to land I am perfectly convinced that by the combined care and cleanliness I extracted from the passengers, and the re-vaccination (or the *morale* of it?) succeeded in staying the ravages of the disease, which might have been very fatal in such a crowded ship as ours

Yours respectfully, CARL PROEGLER, M D

Fort Wayne, Ind , January 24, 1886

ASSOCIATION ITEMS

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo , on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By Laws*, Article 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology —Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky , *Secretary*

Obstetrics and Diseases of Women and Children —Dr S C Gordon, Portland, Me , *Chairman*, Dr J F Y Paine, Galveston, Texas *Secretary*

Surgery and Anatomy —Dr Nicholas Senn, Milwaukee, Wis , *Chairman*, Dr H H Mudd, St Louis, Mo , *Secretary*

State Medicine —Dr John H Rauch, Springfield, Ill , *Chairman*, Dr F E Daniel, Austin, Texas, *Secretary*

Ophthalmology Otology, Laryngology —Dr Eugene Smith, Detroit, Mich , *Chairman*, Dr J F Fulton, St Paul, Minn , *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn , *Chairman*, Dr W B Lawrence, Batesville, Ark , *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago Ill , *Chairman*, Dr A E Baldwin, Chicago, Ill , *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made as now, by the nominating Committee

By Dr I N Quimby, N J —Create a new Section, to be known as the Section on Medical Jurisprudence

WM B ATKINSON, M D ,
Permanent Secretary

1400 Pine St , S W cor Broad, Philadelphia

THE PRODUCTION AND PREVENTION OF PERINEAL LACERATIONS DURING LABOR, WITH DESCRIPTION OF AN UNRECOGNIZED FORM[1]

BY HENRY T BYFORD, M D ,
SURGEON TO THE WOMAN S HOSPITAL OF CHICAGO

In order to bring my subject before you within the allotted time, it will be necessary for me to confine myself largely to general statements, and to omit many desirable but time consuming details

First let me call attention to the peculiar qualities of the obstetric perineum, which, during the previous eight or nine months of passive congestion, has undergone an astonishing amount of development The muscular tissue has become hypertrophied, the fascia thickened and strengthened, and the loose connective tissue[2] proliferated, until the vaginal and vulval mucous membrane, under the stimulus of labor, roll out at the vulva, in much the same manner as the mucous membrane of the cervix rolls out at the os during prolonged congestion or inflammation about the broad ligaments Towards the end of the first stage of labor in healthy young primaparæ, the vaginal orifice will admit a small hand with but little more inconvenience than, nine months before, it would have admitted two fingers

For the purpose of illustration we may divide the obstetric perineum into two parts the vulval or external, and the vaginal or internal The vulval portion may be said to be bounded above, or anteriorly, by the labia majora and vestibule, below, or externally, by the cutaneous surface between the thighs, the fourchette and the anus, and behind, or internally, by the muscles of the perineum It is composed mainly of skin, mucous membrane, and loose connective tissue, containing fat, vessels etc The internal or vaginal portion may be said to include the remaining structures belonging to what is ordinarily described as the perineum It is composed of the fascia, muscles, ligaments, etc

In labor, when the occiput presses against the perineal body, so as to put the muscles and fascia slightly upon the stretch, we can, by hooking the finger over the fourchette into the fossa navicularis, and pulling outwards just as a pain is ceasing, and the head commencing to recede, demonstrate two perineal rings The external or vulval ring, formed by the edges of the labia majora and fourchette, is elastic, of a well-defined oval shape, and attached to the pubic bone above the clitoris The internal, or vaginal, ring corresponds with the labia minora and edge of the external perineal muscles and fascia It feels like a whip cord stretched from the clitoris down through one of the labia minora, across the lower edge of the vaginal orifice, up through the other to its starting point In figure 1 these rings are represented as separated below by the finger over the fourchette, as already indicated (The vulval and vaginal tissues about the rings are not drawn)

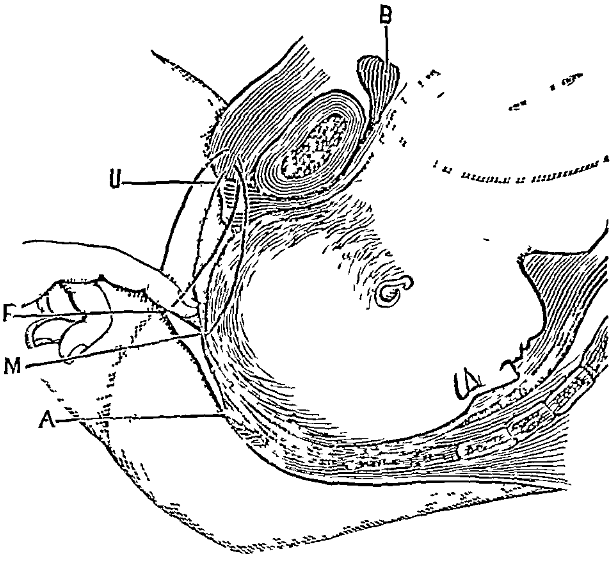

FIGURE 1 —A anus B bladder F fourchette M muscular edge U urethra

When the head recedes so as no longer to put the vaginal orifice on the stretch, the external ring collapses, and the internal ring disappears Later, when the parts bulge and become distended, the internal ring, especially the lower edge, is lost in the flattened or quasi membranous body of the perineum, as in figure 2 But of course it has a definite place, viz , the beginning of the muscular tissue, and extends as far below the fourchette as the length of the antero posterior diameter of the somewhat stretched fossa navicularis, which connects them internally

---

[1] Read before the Chicago Medical Society February 15 1886

The term fascia here is confined to the firmer tissue and not to loose connective tissue to facilitate distinction of parts

Above or external to this vaginal, or internal, ring there is, practically speaking, no muscular tissue, but only skin, mucous membrane, loose connective tissue, fat, vessels, etc

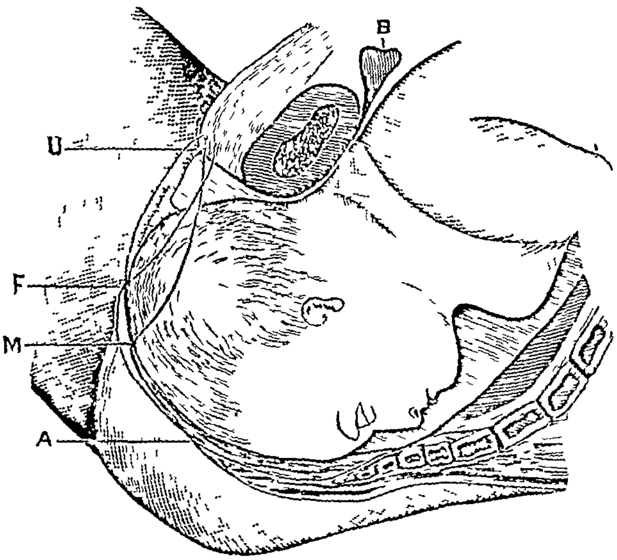

Figure 2 —A anus B bladder F, fourchette M, muscular edge U, urethra (After Schröder)

When the perineum becomes stretched four to five inches antero posteriorly, the lower edges of the rings become still farther separated, and more than an inch of the upper edge of this quasi-membrane is devoid of muscular structure, or firm fascia, as seen in figure 3 It will be noticed that the external ring remains the smaller of the two

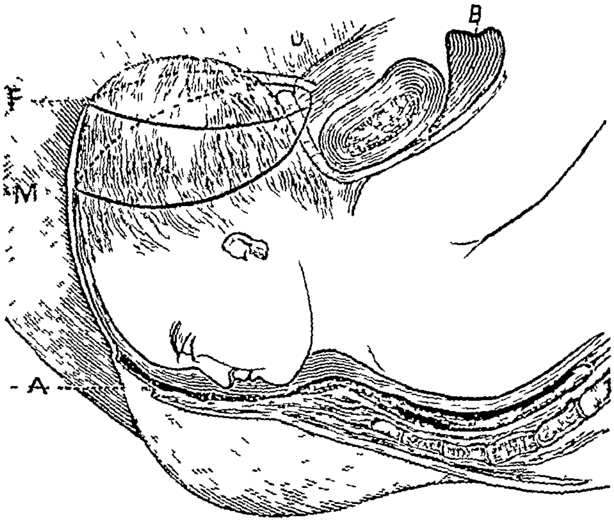

Figure 3 —A anus B, bladder F fourchette M, muscular edge U, urethra (After Schroder)

In determining how the perineum will be affected in labor, we must take into consideration its advance over the pelvic floor, where its direct descent is arrested If the progress of labor at this stage be slow, the liquor amnii, pressing under the chin of the fœtus, will have time to extend the head before the propelling force will have driven the occiput forwards, so as to put the perineum very much upon the stretch When this submental pressure has produced extension as far as it is capable, if the orifice of the parturient canal be sufficiently relaxed or dilated for the apex to engage in it, then the head will easily pass through

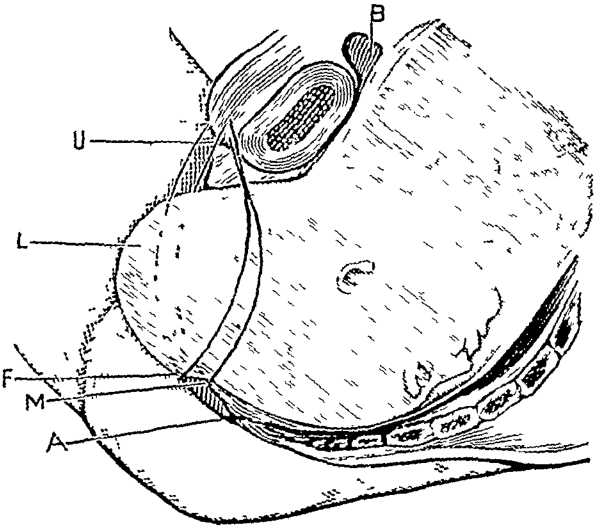

Figure 4 —A, anus B bladder F fourchette L liq amnii M muscular edge U, urethra

it (figure 4) If, however, this orifice be not so relaxed or dilated, then the advancing fœtal head will stretch the perineum from four to five inches antero posteriorly, push the fourchette upwards instead of downwards, and drive the perineal rings before it, instead of dilating them and passing through them, and will cover itself with the flattened perineum, in which the muscular fibres are separated, and the fascia stretched to their limit of resistance (Compare figures 2 and 3 with figure 4) As the forehead passes beyond the coccyx and ligaments, the propelling force acts against this quasi membrane somewhere near the region of the anus, for there is now no directing force left except these attenuated muscles and fascia of the perineum

Now if the pains still be moderate and the tissues unusually strong and elastic, they will finally work up the occiput and draw the edges of the vulvar opening over the head But the difficulty is this If the pains be moderate, their pressure being against the neighborhood of the perineal centre of resistance, is counteracted by the almost direct counter-pressure from that centre, and the retractibility of the over stretched and flattened tissues being but feeble, the head remains almost stationary until, as Barnes expresses it, "the circulation becomes impeded, and, after a time, the tissue half necrosed, becomes as brittle as wet brown paper, yielding under the slightest force" ("Obstetric Medicine and Surgery") Rupture is thus almost certain to result If, on the other hand, the pains be very strong, the resistance at the perineal centre is not powerful enough, and a rupture must occur The lost link in the delivery of the head is thus seen to be the absence of an efficient directing force towards the vulval outlet Or, to express it differently, the head has got beyond the reach of its efficient directing forces, before it is delivered This great mistake of nature, as it thus appears, has led to the invention of numerous devices for supporting or, more properly speaking, managing the perineum

There are five methods of doing this

1 Supplying the directing force, by pressing up the head so as to hold the sub occiput under and against the pubic arch

2 Supplementing the resisting force of the perineal centre by pressing against the advancing head, and thus gaining time for relaxation above

3 Goodell's manœuvre of pulling forward the deeper portions of the perineum, and so diminishing the tension

4 Artificial dilatation

5 A combination or modification of some of these four methods for the purpose of securing the delivery of the head between pains

Almost all lacerations that occur may be described under three heads Lacerations of the vulval perineum, of the vaginal perineum, and compound lacerations, or those which involve both of the structures

Laceration of the Vulval or External Perineum — We may have a rupture of the perineum extending from the external to the internal perineal rings, viz, through the mucous membrane of the fossa navicularis down to the edge of the muscles (from F to M, figure 3), and through a corresponding amount of skin externally After delivery the torn surfaces represent two isosceles triangles, whose bases meet in the median line, and whose apices are the torn corners of the fourchette The tear through the cutaneous surface will in some cases be extended much further, laying open the loose connective tissue down to the external anal sphincter In addition to this lesion we may have a transverse rupture across the posterior portion of the vestibule, just in front of the vaginal orifice, giving to an almost harmless form of laceration an exceedingly ragged and threatening appearance, especially in fat persons

Such lacerations are produced when the perineum is stretched from four to five inches antero-posteriorly, and the internal, or vaginal, ring being larger and extending about an inch and a half lower than the external, or vulval, ring, suddenly slips over the advancing forehead and drags the insufficiently dilated vulval ring so rapidly after it as to tear it The transverse rupture may occur first, and the other afterwards, or efficient management may enable the head, and even the shoulders, to be born without tearing through much, if any, of the skin Forceps, by rapid extraction or faulty shape, rupture these parts in a large percentage of cases in which they are used

The simplest and most rational way of preventing this form of laceration is to stretch the external, or vulval, ring until its lower edge corresponds to the lower edge of the internal, or vaginal, ring, and keep it there Both rings being practically of the same size, will then slip over the head together, and the external perineum be protected behind the internal

Laceration of the Vaginal Perineum —We may have lacerations of the vaginal perineum involving the vaginal mucous membrane only, or the submucous tissues only, or both together

The mucous membrane may give way from friction against the head, or from over distension, yet need not concern us here unless it involve muscles and fascia underneath They are produced by a rapid advance of the head not giving time for normal stretching, or by the failure of a directing force to push the occiput above the upper edge of the muscles and fascia Just as the fascia gives way in the median line, a falling off in the pain, a timely management of the perineum, or a relaxed condition of the outlet, either by checking the too rapid advance or finally directing the occiput through the vulva, allows of delivery without extension of the rupture through the vulva and skin

In this class belongs the variety described by T A Emmet, in which a transverse, or circular, laceration takes place at the internal or vaginal ring, separating "the pelvic fascia just where it is reflected from the sulcus on each side over the muscles at the vaginal outlet" (*Medical News*, January 23, 1886) When this "transverse tear takes place, and the head continues to advance, the connective tissue between these muscles separates, and the muscles themselves are drawn aside, as a curtain, with often not the slightest injury to the skin in front, or the mucous coat of the vaginal canal" (Op cit)

If, however, the vaginal mucous membrane be sufficiently loose and voluminous to remain intact during the separation of fascia along the median line, or the rending of muscle laterally, and the progress of the occiput be then checked and guided by a proper directing force, we may have a purely sub mucous rupture But we may also have a descent of the head which will not be rapid enough to thus tear whole muscles apart, yet so rapid that, when the perineum is stretched to its utmost limit, and the line of advance of the head is pointing towards the perineal centre of resistance, the muscles and fascia will become over-distended, and the fibres and tissues give way all through the membranous cap without implicating either the vaginal or cutaneous surfaces Such is not a very uncommon occurrence in malpresentations, and in forward rotations of the occiput The main evidence of this form of diffuse laceration is a soft and dilated condition of the parts, persisting after several hours have elapsed, when we expect at least some evidence of returning tonicity The condition is similar to that of the anus after one of those rapid dilatations from which the sphincter never recovers its former contractibility

Sometimes the posterior tissues are thus lacerated, especially along the curve of the advancing forehead, or of the forward rotating occiput, without any injury to muscles about the vaginal outlet I have known the sphincter ani, in such cases, to require many weeks to recover its power to retain thin fluids The expulsive power of the lower rectum has been generally lost, at the same time Sometimes, on the other hand, the muscles about the vaginal orifice will be the only ones to suffer While these diffuse submucous lacerations, whether general or regional, have not been recognized as lacerations, their effects have been noted They have been called "over distension of the entire pelvic floor" (Mundé), "overstretched muscles and fascia" (Emmet, Polk), "subinvolution of the uterus and vagina" (Murray, Polk, Cleveland, and others), etc

In order to bring the ends of broken fibres together, the perineal body should be gathered up by two or three stitches taken from the cutaneous surface, and avoiding puncture of the vaginal and rectal mucous membranes Otherwise normal involution and contraction may never occur, and permanent displacements of the pelvic viscera will result The perineal tissue may then be likened to a worn out elastic suspender, in which the rubber threads are broken and the elasticity gone Its length may be reduced by removing a piece and sewing the ends together, but its elasticity can never be restored without putting new rubber into it A fortunate circumstance in connection with such cases is that in some portion of the tissues enough unruptured muscular fibres, or uninjured fascia, may be left to act with the skin as a brace to the rest, and, with the aid of hot douches at 115° to 120° F , and rest in bed, may restore a fair degree of usefulness to the perineum

Care, however, must be taken not to confound this form of laceration with that condition of the parts in old primiparæ, in which there is but little or no rupture of muscular fibre, or of the superficies, but extensive and severe bruising, and a subsequent delay in contraction until the preventing inflammatory induration abates Contraction may not commence for several, days and may not be completed for a couple of weeks In such cases the parts are of course very much discolored and benumbed The perineum seems like a thick piece of soaked or softened leather, and retains a somewhat wrinkled cap shape for many hours The introduction of stitches to draw the parts, thus injured, into shape is not only difficult, but decidedly harmful

Laceration of the vaginal perineum is prevented by securing a slow advance of the head over the deeper and posterior portions, and by directing the occiput upwards, under the pubic arch The proper way to secure this directing force is to dilate the vulval and vaginal rings, so that the occiput will engage in them before the forehead has got beyond the ligamentous perineum Then the lower edges of the two rings become a directing power and lift the occiput up under the symphysis through the already dilated outlet This descent of the lower edge of the rings brings the tissues together in a solid mass near the anus, and renders them capable of meeting any ordinary propelling force without danger of rupturing The meddlesome and unnatural practice of using hot vaginal douches, for relaxing the perineum before delivery, cannot be too strongly condemned They wash out the natural secretions and leave a comparatively dry and irritable mucous membrane, thus increasing friction and danger, they either contract the tissues or lessen their tonicity, seldom relaxing without weakening, as does a normal advance and recession of the ovum, they can with difficulty be used without increasing the discomfort and anxiety of the patient, they are less efficient for the relief of irritability of the parts than hot applications to the abdomen and external perineum, or hot hip baths

Compound Lacerations —Of the remaining, class of perineal lacerations, or those in which both the vulval and vaginal portions are concerned, the simplest form is that in which the superficial muscular fibres give way in the median line along with the fourchette This occurs with a rapid delivery of the head, as in forceps cases, and especially during great bulging of the perineum, when the posterior portions have been dilated, and the last few insufficiently dilated fibres about the vaginal ring unable to stand the stress of a strong pain The advancing forehead may extend the laceration down to or through the sphincter ani Emmett's T shaped laceration may result from this kind of strain, and then involve the vulval portions Or the laceration may commence in the vagina, below the vaginal orifice, and then be completed externally by the advancing head or shoulders Or if pains be strong, and particularly if the sacrum and coccyx be insufficiently curved, the head may push on through the perineum at the sphincter of the anus, and leave an upper portion intact Or the head may rapidly distend the perineum above the anal sphincter until a central rupture will occur, and then be made to pass through the vulval orifice without doing any further injury But the head and body of a child can hardly pass through a central median rupture without involving either the sphincter below or the septum above Finally, we may have a diffuse submucous laceration, becoming complicated, later, with other varieties

These, though by no means all, may, I think, be taken as a representation of the usual forms, and methods of occurrence, of perineal lacerations Prevention, applied to them as a class would, according to the observations presented, involve two principles

1 To make the advance of the head slow enough to allow the parts to dilate to their utmost without tearing

2 To secure sufficient dilatation or relaxation of the vulval and vaginal orifices to bring their axes to correspond with the axis of the parturient canal, so as to enable the head, as it gets beyond the influence of uterine and pelvic directing forces (the amniotic fluid, the pubes, sacrum, coccyx, ligamentous perineum, etc), to find a directing force in the vulval and vaginal orifices or rings

In endeavoring to diminish the rapidity of the progress of the head, it is well to take two points into consideration 1 That uterine action becomes more efficient, as labor advances, on account of the increased length and frequency, rather than the increased force, of the contractions (Schatz) 2 That when the head is capped by the membranous perineum, and therefore is not delivered until it has passed entirely beyond the bony pelvis (figure 3), the uterine contractions have at last almost no direct effect upon its advance, and the abdominal pressure or straining of the mother becomes the chief propelling force (Schroder).

Hence, if we wish to diminish the propelling power during the passage of the head through the pelvis, we may often with advantage give remedies which will act between the pains to diminish their frequency, such as opium, chloral, etc., yet without very much affecting their force. Chloroform, given only during pains, diminishes their force without much affecting their frequency. Later, when the abdominal muscles are the prime forces, we may regulate the advance of the head by controlling them.

The prevalent practice of accelerating the progress of labor until the head greatly distends the perineum, and then using counter pressure to keep the vulva from being lacerated, is to deliberately injure the pelvic floor, and then court rupture of the uterus.

Perhaps the best means of securing a normally slow advance of the head is to preserve the pouch of membranes. This may be done by keeping the patient quiet, discouraging all violent bearing down efforts, making but few digital examinations between, and none at all during pains.

Artificial dilatation of the vulval and vaginal orifices has been advocated by Ernest Trestrail (1875), Mossman (1880), Alex. Duke (1883), and Alfred Carr (1883). Latterly, Professor Leon Dumas has developed a very efficient method of digital dilatation of these orifices, and has practiced it with gratifying results (*Montpellier Medical*, August, 1883,—"Dilatation Præ fœtale de la Vulve"). In my own practice I utilize the pouch of membranes for this purpose also. The vulval and vaginal orifices, being relaxed and everted, are, in most normal cases, less resisting to the pouch than was the os uteri. After being dilated by the pouch, they allow of the rapid passage of the head, thus shortening, and greatly lessening, the usual anguish of the last moments of labor, and reversing the fashionable mode of hurrying up the second stage to save pain, and then checking the advancing head at the final period of severest suffering.

A comparison of figures 3 and 4 will show that when the bag of waters persists, the perineal rings are better prepared for the delivery of the head while the forehead is still on the sacrum, than they are after the chin has passed the coccyx, in those cases where the membranes have been ruptured at the end of the first stage. Besides this, the head has a third less distance to travel during the second stage until born, and thus takes a third less time at a given rate of advance.

In thus advocating a bringing down of the fourchette, I only seek for an imitation, in all cases, of the mechanism that sometimes occurs in young primiparæ, and often in multiparæ, where the vulval and vaginal outlets are normally, and therefore greatly, relaxed, and where neither pouch presents nor fingers interfere. There is much less work either for the pouch, if left alone, or the fingers, if *properly* used, than is generally supposed. But that little work is often of prime importance.

3100 Forest Ave.

A PLEA IN BEHALF OF A NAVAL HOSPITAL FOR INEBRIATES[1]

BY FREDERICK HORNER, M.D.,

OF MARSHALL, VIRGINIA.

In this paper it is proposed to discuss: *First*, the history and origin of hospitals for inebriates; *Secondly*, the presentation of facts to prove that inebriety is a disease; *Thirdly*, the value and results of institutional treatment; and *Fourthly*, the present necessity of a special hospital for the treatment of inebriates of the Navy.

First.—Dr. T. D. Crothers, in a paper read before the London Branch of the British Medical Association, states that "the earliest organized effort in modern times to prevent inebriety was a temperance society which began in New York State in 1828." I may add that two years previously, in 1826, a like organization was started in Boston. The object of these societies was to aid others in pledging themselves to abstain from the use of all intoxicants, and to help each other to carry out this resolution. The Washington societies began in 1840; this movement was greatly promoted by the labors of Father Mathew, an Irish prelate, by Mr. Gough, and Neal Dow, who gave to us the Maine liquor law. Subsequently friends and Sons of Temperance carried on this great work, and since the late civil war the Gospel Temperance and Good Templar societies, perfecting the system which at present embraces the social, moral and religious elements of man's nature. The need is for these classes fully to comprehend the fact that inebriety is a true disease—a widespread epidemic—and to be successfully treated comes within the domain of preventive medicine, and to be relieved and cured must be submitted to the treatment of special and fully enlightened physicians. In the exhaustive address of Dr. Crothers, he adds that "the first period, the rational or scientific epoch, began in 1790, when Dr. Rush, a distinguished physician of Philadelphia, urged that inebriety was a disease and should be studied as such; a physiological and not a moral condition. In Europe this theory was taken up and made the subject of several papers which have become historical."

In 1852, Dr. J. Edward Turner projected the first asylum for the medical care and treatment of inebriates. A new era dawned when the labors of this great philanthropist culminated in the opening of the New York State Hospital. During its brief existence of fourteen years 2,344 inebriates were treated. This enterprise attracted the attention of the world, and clearly demonstrated the disease of inebriety and its curability. In 1859 a similar hospital was begun in Boston, now known as the famous Washingtonian Home, with Dr. Albert Day as Superintendent. During the twenty-five years of its existence almost 8,000 patients have been cared for, "some of whom are now heard from, now honored citizens and performing well the duties of life." During fifteen years the Binghamton Asylum received 7,000 patients for treatment, and from the study of over 2,000 cases five years after the period of treatment in the asylum, sixty-two per centum were found to be temperate and sober There are thirty asylums for the treatment of inebriates in America Some of them are small and empirical in their theories, and many of them are broadly scientific in plans and appliances, one of the largest is for women, and when completed will contain 300 rooms The late Dr J Marion Sims was President of this institution, which is located in Connecticut All of these asylums, remarks Dr Crothers in the Report from which these details are quoted, "suffer from want of legal aid to restrain fully such cases, though everywhere these asylums are building up public sentiment in the direction of physical means and methods of treatment The first effort to study the facts as they appeared from a scientific inquiry began in 1870 in the organization of the American Association for the Cure of Inebriates This Association is composed of physicians who accept the general principle that inebriety is a disease, and is curable as other diseases are To this end asylums are essential, or special quarantine stations where the victim can be housed and receive exact physical care, until the causes are removed and the patient restored—the victim himself being held responsible, like the small pox patient, to use every means for recovering "

---

[1] Read before the Naval Medical Society.

Legal enactments in Europe and in this country have been passed, giving full control over the inebriate—the most advanced of which are in the State of Connecticut and in New South Wales Of the thirty asylums in the United States established during the past quarter of a century, twenty six survive The necessity of hospital treatment for inebriety is thus established beyond all question Public sentiment is enlightened, and under the inspiration of a Christian civilization over a thousand temperance coffee and lodging rooms and Sailors' Homes where no liquor is sold have been opened in this country By these efforts, they recognize the value of physical aid, the necessity of food and rest in order to restore the diseased will The Women's Christian Union maintains most of these places In these Homes, the value of a single day's restraint, with good food and quiet rest, is seen in the help to overcome the diseased appetite They are literally the first efforts of the masses to treat inebriety by rational means, and the beginning of a great movement to establish hospitals for all

Secondly the presentation of facts to prove that inebriety is a disease—The writings of the ancient Greeks and Romans sustain this proposition Herodotus wrote that "drunkenness showed that both the body and soul were sick, and had destroyed many kings and noble people " The Greeks enacted laws forbidding women to use wine In the writings of the thirteenth century drunkenness and madness were mentioned as synonymous terms In 1747 Condillac, a French author, declared that the State should recognize and provide means for its treatment, "since the impulse to drink was, like insanity, an affection of the brain " In 1790, Dr Benjamin Rush sustained this theory by a long train of reasoning He divided the disease into acute and chronic forms, giving many of the causes, among which heredity was prominent, and urged that special measures be taken in the treatment, and in a hospital for the purpose In 1802, Dr Cabanis, of Paris, wrote "that inebriety, like insanity, was a distinct form of mental disorder needing medical care," an opinion sustained also by Prof Platner, of Leipzig, who claimed that the insane impulse of the drunkard ought to be studied by the light of science Esquirol, in 1818, described a condition of the nervous system in which inebriety was sure to follow

To two eminent American physicians, Albert Day and T D Crothers, may be awarded the credit of establishing beyond all questioning the facts to prove that inebriety is a disease In a paper, "Inebriety and its Cure," read by Dr Day before the Suffolk District Society, he says Dipsomania is a term applied to a peculiar form of insanity, designating that uncontrollable impulse towards the use of intoxicating liquors which is felt by some persons at certain periods, and contradistinguished from the craving thirst of the daily moderate drinker *Alcoholism* is the name of all diseases in any way found to be due to the use of alcohol, and applies to the collective symptoms of a disordered condition of the mental, moral and sensory functions of the nervous system, these symptoms, according to Dr Magnus Huss, of Stockholm, in his work on "Alcoholism," may assume a chronic form, and without being immediately connected with any organic manifestations of the central or peripheric portions of the nervous system which may be detected during life or discovered after death by ocular inspection Dr Crothers claims that "all the symptoms of inebriety are incidental to the toxic effects of alcohol, marked by psychical and pathological changes, and the inability of the patient to cease the use of spirits is because of the nerve degeneration which has occurred, then follow functional and organic disturbances From hereditary causes there may be also further proofs of a defective organism, that inebriety is an inherited disease can be clearly proved The poorer classes, from lack of suitable nutriment, resort to stimulants, while the more wealthy from continuous excess develop nutrient degenerations The over mental work and sedentary habits of literary men of unstable mental organization, disordered emotional faculties and unbalanced nutritive functions, constituting the inebriate diathesis, sometimes prove to be causes affecting injuriously the offspring and predisposing to inebriety The organic degenerations are marked by anæmia, neuralgia, and a sudden insane impulse for intoxicants

As inebriety comes on by degrees, the physical condition of the victims of the disease is of great significance The shock arising from injury of the brain or spinal cord by a blow or fall, *coup de soleil*, railroad accident, from the effects of lightning, or reverse of circumstances followed by neurasthenia and ill health, if treated with alcohol, may develop the symptoms of acute and even chronic inebriety The religious revivalist, the disappointed student, and the business man who fails, are examples of the classes of mankind who become victims of this disease—a disease traceable often to conditions of exhaustion of the brain Dyspepsia, which disturbs the nutritive functions of the body, is a predisposing cause, and induces a condition happily designated by that profound expounder of this subject, Dr Crothers, "psychical traumatism," in which the brain and nervous system have lost some power of restoration by which their integrity is preserved, and take on conditions favorable to the development of inebriety At first alcohol is used for its sedative property, second, to relieve the pain of neuralgia or gastralgia Hence the world wide resort to "bitters," so lauded by empirics

Among the predisposing causes may be cited bad influences in the early training of the young Like many other diseases, it is more prevalent at certain periods of life—that of puberty is full of danger It appears, according to Dr Mason's statistics of 250 cases, most frequently in ages from 15 to 25 and from 30 to 35 years The craving or desire for spirits is periodical with some individuals A seaman, Noah like, thus suffers when his cruise or voyage ends this class sometimes lose all consciousness of right and wrong and have no control over the actions of the mind or body, and become insane or criminal Firemen and night workers soon become inebriates Dr Day, in his Report of the Washingtonian Home, 1884, says "the inebriated man appears to act the part of one deranged in intellect, body and mind alike suffer, and a hideous list of nervous failings prey upon his shattered frame and prove fatal in the end" He adds that "the public must look to the medical profession for proofs that inebriety is a disease and is largely the outcome of physical injury It begets various forms of insanity, transmits to progeny a defective brain and an ever-present anæsthesia, wherein the coordinating structures are impaired in substance or in function by the intervention of hyperplasia, excessive cell formation of the interstitial tissue, the unoccupied spaces between the molecules A brain so injured ministers to moral incapacity, ending in a morally depraved character Criminals by birth, though they may never drink, they are thieves and perjurers, and, alas, it may be asserted that the whole race of man now, with few exceptions, by the drinking habit and the abuse of the liquor traffic, is tainted with alcoholic disease from which come poverty, disease, crime, and the most burdensome taxation Inebriety is a foul disease, more destructive to human life than all other diseases combined, enslaving mankind in bondage second only to what Satan achieved for Adam's race in Eden" Dr Frederick C Shattuck says "the high mortality of acute pneumonia in the intemperate is no new observation, but the facts would seem to show that alcoholic excess is not only an important factor in determining the issue of this disease, but that it is often of itself the actual cause of it Thus it is that pneumonia owning this origin is at all ages the most fatal form of the disease known to us"

Professor Christison, of Edinburgh, declares "I recognize certain diseases which originate in the vice of drunkenness alone, which are delirium tremens, cirrhosis of the liver, many cases of Bright's disease of the kidneys, and the dipsomania of insane drunkenness, and also other diseases in regard to which excess in intoxicants acts as a powerful predisposing cause, such as gout, gravel, aneurism, apoplexy, epilepso, cystitis, erysipelas, spreading cellular inflammation, tendencies of wounds and sores to gangrene, and inability to resist the diseases at large" In examples of epidemic continued fevers he had known but a single case of an intemperate man of 40 and upwards to recover Four fifths of his cases of Bright's disease were produced by alcohol All practicing physicians who have treated epidemic cholera or yellow fever know that the maximum mortality occurs to the intemperate classes of society

Dr C Murchison, the author of an excellent treatise on "Continued Fevers in Great Britain," says "A single act of intoxication or debauch predisposes to typhus," adding that there is no greater error than to imagine that a liberal allowance of alcoholic stimulants fortifies the system against contagious diseases In Dr Murchison's "Lectures on Functional Diseases of the Liver" before the Royal College of Physicians in London, it is asserted that the prevalence of beer and spirit drinking and consequent liver clogging accounts for the widespread use of countless forms of patent medicines These are all of a purgative character, and give temporary relief to the overwrought liver, but help to shorten life

Dr Norman Kerr, in the discussion of diseases due to the abuse of alcohol, states that probably sixty per centum of the cases of erysipelas were occasioned by it The use of beer produces a species of degeneration of all the organism—fatty deposits, diminished circulation, congestion of the viscera and local inflammation of both the liver and kidneys Intellectually sometimes a stupor amounting to paralysis, and arrest of the reason, changing all the higher faculties into mere animalism, selfish and sluggish, varied only by paroxysms of anger that are brutal Its constant use gives the body no recuperation, but steadily lowers the vital forces It has been remarked that the most dangerous class of ruffians in our large cities are beer drinkers Hence the conclusion that inebriety leads to criminal acts is undoubtedly true

Dr B W Richardson said before the Edinburgh Society of Arts "Alcohol, instead of raising, lowers the temperature of the body After a drunken stupor it takes three days to restore the natural warmth The development of fat from its use is simply due to structural degeneration of the vital organs Hence alcohol is not in a proper sense a food It accelerates the action of the heart from 100,000 to 125,000, followed by a proportionate weakness The heart becomes enlarged and its valves disordered, and the brain, by the increased flow of blood to it, is rendered for the time more active and is succeeded by greater feebleness, which demands the repetition of the stimulus Among the effects of deterioration in those who drink moderately are various neuralgic pains, the worst form of indigestion, and wakefulness At a later stage of drunkenness, not a single organ of the body escapes disorganization of its vital structure, though heredity or other conditions may cause a seeming concentration on a particular organ—the liver, the kidney, the lungs, the heart, brain or spinal cord." This author concludes that if any form of alcohol do really for the moment cheer the weary and impart a flush of transient pleasure to one who craves for mirth, its influence, an infinitesimal advantage, is obtained by the side often of an infinity of evil for which there is no compensation, if a cure. The proofs thus furnished by the writings of the most eminent medical authorities, that inebriety is a disease, and also productive of other diseases, may be summed up in the utterances of Dr. Joseph Parish, that it cannot be denied that, 1, it is a disease, and with specific symptoms; 2, there is a condition of the nervous system with which some men are born that predisposes them to alcoholic indulgence. Hence the inebriate must be treated as other diseased human beings, and not ostracized by society and branded as a criminal, and be driven an outcast beyond the pale of human sympathy. In his behalf the laws of hygiene must be taught in their highest sense, and a curative and humane treatment be adopted.

These opinions are also ably maintained by Dr. Albert Day, who declares that "the inheritance of inebriety follows the same laws as other nervous diseases, a predisposing cause being a civilization at the present day demanding a great expenditure of nerve force and brain work, while among the exciting causes are alcohol, opiates and chloral, which, by acting in a secondary manner upon a low nerve power, produce the diseased condition known as dipsomania. The disease never exhibits itself till alcohol has been consumed, resulting in the poison of the blood and the arrest of the healthy operation of the nervous system. It attacks the higher faculties, dethrones the reason, retrogrades its victim to a level with the brute, and in its chronic form is inducive of mania a potu, epilepsy and insanity. If cholera and other plagues have slain their thousands, inebriety annually destroys its ten thousands. The whole subject embraced within this division of my topic comes within the domain of *preventive medicine* as clearly as any single one of the zymotic diseases, and so soon as the medical profession will direct their attention to its recognition, prevention and cure, will mankind be freed from the most dire scourge which can afflict the human race.

Thirdly. The value and results of institutional treatment.—On this part of my subject I regard the testimony of Dr. Albert Day as furnishing an unanswerable argument in favor of the value and success of institutional treatment, as tried during the past twenty-eight years at the Washingtonian Home. Dr. Day, in his Report for 1885, says that one of the earliest results of hospital treatment was the discovery that inebriety is a disease rather than a vice proceeding from the creation of an artificial appetite, and it never exhibits itself until alcohol has been consumed. Dr. Day has treated over 10,000 cases, and by statistics demonstrates that asylums, properly conducted, are an actual saving to the State in dollars and cents. The instances of relapses have been less than is generally supposed. This method has at least proved to be the best yet discovered to ensure a complete and permanent cure for reforming the evil. The victim is thereby withdrawn from associations of temptation, is received with kindness, and having first expelled the evil within him, is reawakened to self respect, and after a time is restored to the community with a sound mind in a sound body, and becomes again an active worker in the great human hive—useful to himself and a source of happiness to his friends. This eminent physician and philanthropist adds that in the treatment of his patients he aims to promote in them true virtue, total abstinence and true piety, to stimulate their own exertions for a better knowledge of God and His laws, and for a determined self control. In this era of practical atheism and morbid materialism among a certain class of physicians, the sentiment expressive of faith in God and His word which Dr. Day commends to his patients is deserving of praise, since the true physician has ever to remember that he is only the honored instrument of a superior power in relieving maladies of the body or mind; and, after all, it is only "God who healeth our diseases." It can readily be proved that all attempts to treat successfully and to cure inebriety in civil practice or on board ship have failed. While due prominence has already been given in this paper to the treatment of the inebriate in an asylum, and full concession made to the wisdom of those who have advocated institutional treatment and yet deny that there is any vice connected with the disease, which is called inebriety, we are instructed to the contrary plainly by the teachings of the Bible. This sacred book declares that drunkenness is a sin so offensive to the Diety that by Hebrew law the victim was stoned to death, and under the new testament, or Gospel, dispensation, such an offender will at death be deprived of the joys of Heaven. Hence, as Christian physicians bearing the mantle of the great Physician who alone delegates to us the wisdom and force to heal the drunkard's bodily ailment, we can, also, present to his heart and conscience the consolations of the Christian religion. Thereby we strive to lift him to a higher life and remind him of the solemn warning which the Bible conveys, that "no drunkard shall enter the kingdom of heaven."

Fourthly. The present necessity of a Special Hospital for the treatment of inebriates of the Navy.—In a late letter received from Dr. Albert Day, he says: "It seems to me fortunate that you are to present the subject of institutional treatment for the unfortunate victims of inebriety in our Army and Navy. A large number of men have come under my care during the past thirty years, and in all respects from inebriety they are the best and most intelligent in the service. Should the Government establish such an institution we should hear less of insubordination, disgraceful conduct and self destruction. Under proper asylum treatment a large percentage of these men could be saved to the service and their families." He adds: 'I have been engaged in this work nearly thirty years and I am approaching the end. I can truly say that I am more satisfied with the results of my life's labor than I at the first anticipated But the work has been a success I often meet persons rescued from the most degraded form of intemperance, they are now worthy and honored citizens, who can date their cure back to twenty or more years "

It required three quarters of a century before naval authorities established a hospital for the insane of the public service The suggestion first made by that great philanthropist, Miss Dix, was successfully carried into effect in 1858 by Dr Charles H Nichols There can be no question from the facts presented in this paper, that for nearly thirty years the experiment of hospitals for inebriates in nearly every State in the Union has been successfully demonstrated in this country as well as in Europe The Naval Surgeon should, in the practice of *preventive medicine*, be convinced that the disease inebriety, occurring in the line of duty to officers or seamen, should have the benefit of special treatment in a hospital instituted for this special disease The Annual Report of the Surgeon-General of the Navy notices a certain number of cases of acute and chronic alcoholism, and of delirium tremens, say one fifth, rightly included under the head of "Poisons," as occurring in the various squadrons at home and abroad, at the navy yards and in naval hospitals Among this number there must be cases discharged uncured In the North Atlantic Squadron, under the head of "Poisons," which includes acute alcoholism, *vulnus venatum*, *colica pictonum*, etc , the ratio per 1000 of this class is set down in the Report as 10 In the European Squadron, under the head of "Poisons," 17 per 1000 is the number given, 13 admitted, 12 discharged and 1 invalided The Report concerning the sanitary condition of the various hospitals also furnishes examples of acute and chronic alcoholism and ebriositas, 31 cases admitted, 30 discharged, and 1 invalided Such facts are suggestive that, what ever precautions may be adopted by the medical staff of the Navy to eliminate inebriety from the public service, the experiment has failed The attempt at treatment on board ship, as in civil practice has also failed, but not so has institutional treatment

Already the naval surgeon has won an advanced position in the departments of sanitary science and of preventive medicine, indeed, he is fully qualified to discharge all professional duties as a surgeon and physician according to all the light which medical and surgical science has reflected upon the human mind Hence the query, will he not be derelict to fail to apply the most enlightened medical and institutional treatment to an inebriate on board ship, as well as in a special hospital, rather than to furnish testimony before a court of inquiry or a court martial as a witness, thereby ensuring the summary disgrace or expulsion from the public service for drunkenness of an efficient officer or a valuable seaman? The latter cruel and, in many instances, unjust method was practiced prior to 1859, though it can not be sanctioned at present In one case, of which the writer was cognizant, the greatest wrong was inflicted upon a talented and efficient naval officer, whose valuable services saved a sloop of-war, with her crew, from shipwreck His exposure to a tropical sun, in an open boat, to discover a safe channel for the escape of the vessel, was of course the occasion of great mental strain On returning to the United States subsequently, can there be any surprise that this officer in an evil hour was tempted to acts of intemperance? And yet the decision of a court martial convicted him of drunkenness, and sent him into the world a disgraced and ruined man.

Finally, the suggestion may be ventured that, at least, one of the various Naval Hospitals now appropriated for the treatment of the sick and wounded might be judiciously set apart for the special care, relief and cure of the unfortunate victims of inebriety of the American Naval Service

A NEW CLOTHING CASE FOR THE SOLDIER

BY W THORNTON PARKER, M D ,

OF NEWPORT R I LATE ASSISTANT SURGEON U S ARMY

The science of medicine has for its purpose not only the cure of disease, but, infinitely more important, the prevention of sickness and of suffering Students of the medical profession—and, as long as we are faithful to our calling, we who are known as medical doctors must also be students—investigate matters pertaining to prevention and cure in every direction To one the ability is given to contribute books of instruction, to another records for reference, to others instruments for operative surgery, instruments for diagnosis, appliances for deformities, apparatus for the relief of the injured, appliances to protect against deadly pestilence, and the simpler articles to aid in general hygiene There are many workers, and much material offered for inspection which must prove worthless and useless From the great gathering of the efforts of thousands some things prove of value and are accepted and are permitted to do useful and honorable service All cannot be utilized Some things must be rejected, but the faithful worker brings his offering to the profession and patiently waits the verdict of his peers and of his seniors

The experience which was won by the dreadful War of the Rebellion in this country has had its good effects all over the world The lessons learned by our medical officers and sanitarians have been made use of in every war since, and the valuable records are stored ready for future instruction The study of military hygiene is of the utmost importance The preservation of the health of the soldier, with a view to increasing his effectiveness and diminish the causes which weaken, injure and invalid him, are worthy of the most careful study, investigation and experiment The poetical and romantic in uniform and ceremony must fall before the searching analysis of the practical question All that relates to the soldier, his food, clothing, camp, arms, recreations, duties, physical condition, morality, all these and many more must interest those who have the soldier's real and lasting welfare at heart The soldier, to be effective as a fighting man, must be able to go on the battle-field in a condition of strength and general "smartness" The valuable property of the soldier, called "*esprit de corps*," must suffer very decidedly when the body is exhausted and when the "mob action" is seen on every side

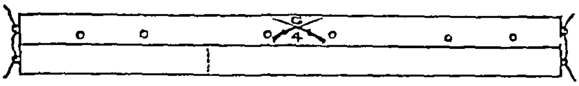
It is the purpose of this paper to treat of only one detail in the soldier's make up, and although that may seem to the general observer unimportant, a more important subject could hardly be considered It was the experience of many army officers, during the War of the Rebellion in the United States, that soldiers, although provided with the best knapsacks which could be manufactured, invariably threw them away upon long marches, together with the clothing contained in them, rather than endure the fearful physical suffering which resulted from carrying them Those who were determined to save some extra clothing did so by wrapping it up in the rolled blanket or overcoat, which they wore over the left shoulder During the Franco Prussian war many regiments transported their extras wrapped in blankets or overcoats and worn swung over the left shoulder The ends of the overcoat or blanket were secured by straps or cords at the right side The right arm and shoulder would therefore remain free for the carrying of the rifle, and easy movement for loading, aiming, firing, charging, and other exercises of the soldier could all be promptly executed The different forms of knapsacks which I have examined, although remarkably similar in appearance in the German, Austrian French, English, Dutch, Italian, Swiss and American armies, are clumsy, heavy, and too fatiguing for the soldier's use in peace, even, much less useful in time of war The necessity for the easy transportation of the soldier's kit by the soldier is often of the greatest importance when in actual warfare and liably to long marches, especially when the quartermaster's train has failed, or when the rapid movement of armies is necessary, without the aid of wagons and horses

The knapsack is especially undesirable because its straps draw heavily against the muscles used in respiration The tugging of pack impedes the act of respiration very greatly, especially when the body is fatigued The oppression caused by the weight of the knapsack, and its interference with normal breathing, is so great that I have seen soldiers faint away and even fall in ranks at Sunday morning inspection, after carrying the knapsack only a short time The distress from the weight of the knapsack often causes a large per cent of stragglers and sick men before the troops even reach the battle field An army is thereby deprived of many men of excellent courage and intelligence who would, by their presence, have aided much in action towards the general success, but whose physical resources were not equal to the dreadful pack on their backs The pressure and contact of the knapsack heats and weakens that portion of the body against which it rests, and after reaching camp or a halt its removal exposes the soldier to additional chances of taking cold

Any one who has witnessed the departure of troops for the war, in what is called *heavy* marching order, must have noticed countless men already nearly tired out, struggling to keep up appearances and bear, in a soldierly way, their "pack" It was an easy matter to estimate how many, from the weight of the knapsack, must soon break down and become useless as fighting men

To remedy some of the defects and dangers which we have been considering, I have devised a "Marching Clothing Case," which very many of the officers of the United States Army, and also officers of the Army of the Union during the war, have examined and highly approved of The Newport Medical Society, at the regular monthly meeting held December 2d, formally approved of this Case, and have recommended it to all army boards for use, instead of the knapsack

The Case is made of light canvas or waterproof cloth, and when completed it weighs but a fraction of the weight of the average knapsack It is manufactured as follows



A strip of cloth four feet long, or four feet six inches is a better length, by sixteen inches wide, is folded to make a pocket six or eight inches deep This is done by making the covering flap lengthwise, and dividing it into three pockets by a few stitches across at a third of its length, making three equal divisions Six buttons hold the flap in place Loops at either end enable the soldier to wear it secured at the ends without its being rolled in blanket or overcoat This Case will hold one pair of drawers, two flannel shirts, two pairs of stockings, towels and other extra pieces of clothing, and the "soldier's book"

It is useful in that it can be worn for days without giving fatigue, and the weight is so evenly distributed that the soldier does not suffer from carrying it or feel disposed to throw it away Upon reaching camp the blanket can be unrolled and the Case hung up or thrown in the corner, the clothing remaining in the Case clean and undisturbed When the clothing is rolled loosely in the blanket, upon reaching camp the blanket is needed and the contents are likely to be scattered about the tent and soiled or ruined with mud and rain

This Clothing Case does away with the necessity for knapsack or clothing bag, and can be manufactured easily and quickly, and at a trifling expense compared with the cost for the manufacture of knapsacks No clothing case could be more easily carried than one suspended from the shoulder It can be used at all times, even in action, and would then offer considerable protection of the vital organs against musket balls

It is intended that this Case be worn in the rolled blanket or overcoat suspended from the left shoulder, giving the right arm full play and allowing, as we have seen, the utmost freedom in the performance of the most important exercises of the manual of arms

Newport, R I, December 1885

MEDICAL PROGRESS.

STRETCHING THE SPHINCTER ANI —At the close of a recent lecture on the "Surgery of the Male Perinæum" MR C G WHEELHOUSE said that by London Surgeons, as a rule, the operation of "stretching the sphincter" is neither recognised, nor taught, nor appreciated, indeed, I have heard of its being scouted, as unsurgical and unnecessary Introduced into Leeds by the late Mr Teale, the practice of "stretching," in preference to "cutting," the sphincter has been upheld for twenty-five years at least, and of late years has rather grown than declined in your favor The principle upon which it is based is, of course, the one formulated and eloquently preached by the late Mr Hilton, that the true cure for parts suffering from irritation is to place them physiologically at rest, and the ground upon which we prefer it is, that by it we can attain our end without causing an external wound, and thereby rendering our patient liable to septic poisoning

Consider, for a moment, the position and office of the sphincter, to guard the rectum from the involuntary discharge or escape of its contents This, so long as the rectum is at peace, it is capable of effecting easily, perfectly, and without strain, and its ordinary action is neither violent, nor spasmodic, nor irritable But suppose some sort of irritation to have arisen in the bowel—acute diarrhœa, chronic ulceration, fissure, fistula, or piles—and what will be the state of the sphincter then? In direct proportion to the amount or of the duration of the continuance of the disease, it will become hypertrophied and strengthened to enable it to maintain its power and its office, and, in time, it comes to be enormously more powerful than is natural, or, were the parts in a healthy condition, necessary

Piles, supposing them to be the cause of the irritation, are perpetually tending to protrusion, and are ceaselessly warring with the muscle, from time to time, when the fæces are passed, the piles are protruded with them, remaining after defæcation in the grasp of the sphincter, they are crushed, and bruised, and become inflamed and painful, and even though they be released from their imprisonment, as they usually are, by the patient, and are returned into the bowel, it is only to continue there the war with the sphincter and to prolong the agony Or, suppose that a painful ulcer or fissure exists within the margin of the anus, and immediately within the anus is their most common seat, what will then be the state of affairs? The discharge from an ulcer or from fissures cannot get away, the sphincter will not permit it to do so, it accumulates and irritates the muscle, this retaliates by increased contraction, and thus the war goes on, to the infinite disadvantage of both parties concerned, the ulcer spreads, the fissure deepens, and the sphincter hypertrophies

Sometimes, in the case of fistulæ, matters do not become quite so accentuated or acute, for the matter finds a vent in the perinæum, beyond the range of the action of the sphincter, and the direct irritation to the muscle is so much the less, but in one and all these cases alike, you will have been, or you will be taught, and every text book you read will reiterate the fact that, for their cure, you may do whatever you will, but you will not succeed until you have put the sphincter at rest, and you are invariably assured that its division with the knife is the only way to do it

Now this is the point which we in Leeds contest We assert, and we assert it upon abundant practical experience, that careful, deliberate, and efficient stretching will do all that incision will do, and, doing it without causing any external wound, will subject the patient to far less risk than is possible by incision Some of you may smile at the idea of there being any risk in so simple an operation as division of the sphincter, but there are such things as accidents, Sir James Paget has most appropriately termed them "catastrophies of surgery," which ought never to be forgotten and should be avoided, where possible, by any amount of foresight on the part of the surgeon One such, in connection with the subject under consideration, happened to me in my early days, and, so profound was the impression it made upon me, that to forget it even now is quite impossible For a painful fissure of the anus, I passed a bistoury along its track, divided its indurated base, and, with that, the resisting sphincter underlying it, but in less than a week my patient, the father of a young family, was dead, having very speedily after the operation been attacked with acute and fatal septicæmia By stretching in preference to cutting, we have it in our power to avoid this risk, at any rate, and, in my experience, the best method of doing it, where possible, is with the fingers, or if need be, the thumbs alone Let the patient be placed fully under the influence of either, and then, according to the amount of the hypertrophy, or the degree of resistance in the sphincter, dilate it steadily, either with the fingers, or with some appropriate instrument, until you have overcome all undue resistance, and can leave the anus soft, patulous, and free from irritable tension

I have heard the question carefully discussed, as to whether the digital or the instrumental method of dilatation is the best Personally I prefer the digital, because, my object being to tear so much of the muscle across (the mucous membrane over it remaining intact) as shall be sufficient to diminish, without destroying its whole power, I can, when my fingers are the instrument used, feel with them when I have done what I wish, and I need do no more But so great is the hypertrophy sometimes, that the fingers, even of the strongest hands, are quite inadequate to the task of overcoming it In such cases I usually dilate steadily first with the instrument till I can withdraw it (wide open) with freedom and without resistance, or, with a tenotomy knife, I divide subcutaneously a given proportion of the hypertrophied muscle, and after that I carry on, where it is necessary, any further dilatation with my fingers —*British Medical Journal*, Feb 6, 1886

A DANGER IN HOUSE SANITATION —The space underneath the floors in dwellings, between the flooring and ceiling of the room below, is a part of the house which receives very little attention from the householder who may pass a considerable amount of time above it Because it is not of much thought, it does not follow that it is not an important object for consideration On the contrary it may become of prime importance in the health preserving qualities of a house

In most houses, there is no attempt made to fill this space The floor is laid on top of the joists, and the lath and plaster is put on the bottom, leaving a long open space between joists, connecting with the space between the studdings and the sides of the building This free connection is almost universal, and is objectionable in every case It permits a free circulation of cellar air all over the system of partitions and assists its general dissemination into the atmosphere of the house It creates an uninterrupted passageway for rats, mice, and other vermin, which often make themselves objectionable, to say the least In case a fire starts in the lower portion of the house from an overheated flue, or other cause, these open passageways offer avenues for the spread of the flames so that before any manifestation of its presence is made, it is far beyond control

These are the most patent objections to the open spaced floors, as constructed in many houses There are others which are more powerful than those recited, which will become perfectly apparent when attention is called to them In houses constructed with open spaces there is an inviting place for dust, dirt, and other impurities to collect, by constant sweeping, scrubbing, and the friction of many feet The modern sanitarian is educated to believe that wherever there is dirt there is danger The constant presence of germs in decomposing animal and vegetable matter, makes the presence of this collection of dirt quite to be feared

Another source of danger is the filling, or deadening, as it is sometimes called, which is used to fill up these spaces when anything is used Manifestly, it should be nothing of a decomposable nature, or a medium which could afford a harbor for vermin

The constant reappearance of a disease in a house or in a room, may be connected with this harbor of refuge for germs beneath the floors These spaces are seldom the recipients of pure air which would oxidize impurities, nor are they much affected by any ordinary disinfecting process It may be urged, then, that all floor-spaces be filled carefully, and when filled, it be with some such material as asbestos, mineral wool, or other matter not apt to become dangerous either from its own decomposition or by the reception of decomposable material —*The Sanitary News*, January, 30, 1886

Dry Dressings for Internal Cavities —Dr Charles F Hutchinson, of Scarborough, says in a note on this subject Dry dressings being now all the fashion, and to my mind most justly so, I wish to draw the attention of the profession to a very simple method of applying, in the dry state, dressings, styptics, etc , to such cavities as the vagina, uterus, and rectum

The only apparatus required is a hollow cacao-butter suppository, which suppositories are made in various sizes, the largest of which will just about hold one drachm of any ordinary powder These hollow suppositories are filled with the powder that may be wished to be used as a dressing, the small lid, after being gently heated, is put on, this when cool remains fixed, and the whole apparatus is then ready to be introduced into the vagina or rectum The heat of the body soon melts the cacao butter, and the powder is then brought, in as dry a state as possible, into direct contact with the parts During the last six months I have used these suppositories most freely, and have been more than satisfied with the result I have tried all sorts of powders, and as the result of my own experience strongly recommend the following, either alone or in various combinations as required

Firstly, as a styptic I most strongly recommend powdered iron alum I generally order one drachm of powdered iron alum and five grains of iodoform, to be well mixed together, the powder to be inserted into a hollow suppository and used as directed In the treatment of uterine hæmorrhage I am convinced there is no remedy of more universal application, and none on which I could with greater confidence rely I have used it in severe hæmorrhage from uterine cancer, bad miscarriage, and in several cases of menorrhagia at the change of life, and it has never yet failed me All that is required is to introduce the suppository as high as possible into the vagina, and there leave it It is as easily applied by the nurse as by the doctor, and is in every way perfectly safe and harmless

Secondly, as a dressing iodoform stands pre eminent, in fact, I now seldom use anything else This, when combined with from a quarter to half a grain of morphia, forms by far the best dressing for uterine cancer that I have yet tried

Thirdly, morphia, either alone, or as I generally now use it, in combination with either or both of the above, is a great aid to the physician and comfort to the patient

After attention has once been drawn to this simple mode of applying these various applications, the numerous uses to which they might be put in the various vaginal, uterine, and rectal discharges and diseases will occur to all I have only very briefly ventured to suggest the use of those in my own hands I have found deserving of confidence I have no doubt that hundreds of the profession are at present using this mode of dressing, but, on the other hand, I know that there are hundreds who are not, and it is to persuade those who have not yet tried them that I venture to bring this subject forward —*The Lancet*, February 15, 1886

The Uses of a Five per Cent Solution of Brucine —In a note on this subject Dr Ralph W Zeiss, of Philadelphia, says that he has arrived at the following conclusions from experiments with a five per cent solution of brucine

1 I have twice applied the solution, by means of a tuft of cotton on a cotton-holder, to painful *furuncles* of the external auditory canal In both cases marked relief was noticed in from two to four minutes, which

lasted for some hours, when the pain slowly returned as before. Skin in these cases not broken.

2. In cases of painful *suppurative otitis* of the middle ear (some five or six in all) the solution gave *some* relief in *all* cases; very *marked* relief from pain, lasting for a number of hours, in two cases. In these patients the solution was passed on the cotton tuft down to the fundus of the canal, and the raw and often bleeding surface carefully and thoroughly mopped.

3. I have used the brucine solution some scores of times in *sensitive conditions* of the auditory canal to render the use of instruments painless. No record was kept of these, but in about one-half the cases the patients volunteered the statement, "It don't hurt as much now," while in the other half no results of any importance were obtained, sensitiveness being in no way lessened.

4. Brucine, in my hands, has proved most useful in lessening or entirely abolishing the pain and burning caused by *applications* of iodine, nitrate of silver, sulphate of copper, and the like to the mucous membrane of the throat and nasal passages. I have repeatedly used it in these cases, perhaps nearly fifty times, and in almost every case relief was noticed, and in the majority of the cases pain and irritation were at once overcome.

5. In one or two cases of *burns* the solution has proved valueless.

6. Painted along the line of incision before opening a shallow abscess, it did no good whatever, the patient suffering as much as usual.

7. Used on the external surface of the body, the five per cent. solution has proved of no value whatever in my hands.

Speaking generally, I do not consider the brucine salt equal in its local effects to the muriate of cocaine. Though more lasting, it is much less reliable, nor does it seem to be so readily absorbed.

In some two or three instances, after liberal applications of brucine to the nasal cavities, patients have complained of having felt wildly "nervous" for some hours afterwards, evidently from the strychnine like effects of the drug. In no other instances were the slightest toxic effects noted, although as much as mv of the solution has been repeatedly used in the middle ear and nasal fossæ.—*Therapeutic Gazette*, Jan. 15, 1886.

MICROSCOPICAL EXAMINATION OF MORBID STRUCTURES.—The busy practitioner who has but little time to spare for elaborate investigation of diseased structure, says DR. W. B. KESTEVEN, and who probably has not the resources of a laboratory at his command, will nevertheless often desire to investigate the minute changes which have resulted from the pathological processes that he has watched to their fatal issue. Too often, indeed, it occurs that prejudice presents an insurmountable bar to the satisfaction of so laudable a curiosity. Another difficulty, moreover, is frequently interposed, under the idea that morbid structures must undergo a process of hardening previously to examination. The plan of hardening, staining, and clearing before mounting for microscopical examination is, however, I suspect, often attended with the alteration of portions of the elementary tissues. The examination of parenchymatous structures, such as liver, kidney, lung, sarcomata, schirrus, etc., can be effected in a few minutes by a ready method, the means of which may be always at hand. A Valentine's knife or a sharp razor will give a sufficiently thin section, which should be placed for two or three minutes in methylin, or aniline blue (not the blue-black). Surplus coloring matter should be washed off in water, and the section is then ready for microscopical examination—if it be desired to preserve the section it can be placed in glycerine, or Farrant's medium. These two staining fluids are valuable agents for the differentiation of structure in tissues prepared in the ready method now described. Cells, nuclei, fibres, and stroma are distinctly marked out. If the aniline, or methylin blue, be not available at the moment, a fairly good substitute may be found in Stephens's blue-black ink. Nervous tissues, such as brain or spinal cord, require for the full and complete examination of local changes that they shall be submitted to the processes of hardening, staining, and clearing, but a tentative, or preliminary examination of the fresh brain may be made by the "handy method" of Dr. Batty Tuke.[1] A small piece of the tissue, of about the size of a pin's head, taken from the supposed morbid portion, should be placed upon a glass slide and pressed down by a thin cover. The cover then being removed, a few drops of "Judson's magenta," or of carmine solution diluted with six or eight times its amount of water, should be mixed up by means of a needle, with the brain tissue and a clean thin cover pressed down upon it, until the substance is so thin as to be translucent. The cells, nuclei, and vessels will take the coloring matter deeply, whilst other structures remain unaffected. Morbid conditions are thereby brought into view—*e. g.*, pigmentary granulation of cells, change of form in nuclei, colloid bodies which refuse the stain, and the imperfectly colored miliary bodies, etc. Having made trials of a large number of staining fluids, the writer has satisfied himself that the two blues above mentioned are the best suited to the ready examination of parenchymatous structure; whilst for sections of hardened brain-substance he has learnt to rely most upon solution of carmine, and next to that upon aniline blue-black.—*Provinc. Med. Journ.*, Jan. 1, 1886.

CHANGES IN THE PUPIL AFTER DEATH.—From an interesting series of original observations upon the eyes of recently dead subjects and upon their behavior under certain physiological stimuli, MR. J. N. MARSHALL draws the following conclusions:

"(1) In most cases, the pupils are dilated at the time of death, the dilatation usually occurring within a short period of the fatal event. Dilatation at an appreciable time after death is quite exceptional. This condition is essentially paralytic and is independent of the state of the pupil during life, whether that is altered by drugs or by disease.

"(2) There is, in the great majority of cases, progressive contraction of the pupil after death. This varies within wide limits, both as regards its period of commencement and the degree of myosis attained

---

[1] British Medical Journal, Sept., 1874.

It usually begins within an hour after death, and continues for the next forty-eight hours. The contraction which is often unequal in the two eyes, is independent of the action of light upon the eye and of the occurrence of rigor mortis.

"(3) The pupil is susceptible to the action of atropine after death, for a period which probably varies with different subjects, but which may be as long as four hours when simple instillation is employed, and perhaps a little longer when the atropine is injected into the anterior chamber. The dilatation begins at about the same time after instillation of the atropine, as it does after instillation during life, but it differs from the dilatation after the latter in that it is of less degree, and that the influence of the atropine passes off sooner and leaves the pupil to follow its usual course.

"(4) The instillation or injection of eserine after death produces contraction of the pupil, but the period after death during which it can act is shorter than in the case of atropine.

"(5) The instillation of ergotine after death has no effect on the pupil, but its injection into the iris or anterior chamber produces contraction of the pupil up to at least two hours after death.

"(6) Pilocarpine injected into the dead eye has a slight myotic action.

"(7) The removal of the aqueous humor after death does not affect the ordinary behavior of the pupil.

"(8) Flaccidity of the iris during life is exceptional, but it is always present after death, and increases from the time of death onward."—*Boston Medical and Surgical Journal*, February 11, 1886.

THE SOURCE OF UREA.—MR. D. W. AITKEN, of Edinburgh, reports the following interesting case:—Early in January, 1886, he was called to see a boy who had, the day previous, received a rather severe blow upon the right lobe of the liver. When seen, he was complaining of much pain in the right hypochondrium. The skin was slightly, and the conjunctiva distinctly, jaundiced. The stools were pale, while the urine was bile colored, and gave the bile reaction with nitric acid; there was no fever. But herein lies the important matter. The urine was highly alkaline. On the addition of nitric acid, there was such violent effervescence, that the froth was forced out of the test-tube, although the urine was not much more than one inch deep. He got his friend, Dr. Drinkwater, to carefully examine the urine. He reported that the alkalinity was due to ammonium carbonate, and, on estimating the urea, he only found 3 per cent.

This evidence seems to him to point strongly to the liver as the seat of producing of urea. Dr. Graves has already reported several cases of absence of urea which he believed to be represented in the urine by the ammonium carbonate, but here we have a history of the organ involved.—*Brit. Med. Jour.*, Feb. 6, 1886.

A MODIFICATION OF FEHLING'S TEST.—BUCHNER has proposed the following modification of Fehling's method for sugar. Many saccharine urines only give an opalescent yellowish-red coloration, and no red precipitate of cuprous oxide, when heated with Fehling's solution, making therefore the presence of sugar appear doubtful. In such cases, the urine is to be boiled with excess of cupric sulphate solution (1:10). The greyish green precipitate is to be separated, and potassic hydrate, or some Fehling's solution, to be added to the filtrate, on boiling which the red suboxide of copper will be deposited, if even a small proportion of sugar be present.—*London Medical Record*, January 15, 1886.

PAINLESS OPERATIONS FOR PHIMOSIS.—DR. W. ROUNDS BARNES, of Binghamton, N. Y., writes that he performed circumcision upon a man 42 years of age, after having previously applied a four per cent. solution of cocaine for twelve minutes to both surfaces of the prepuce along the proposed line of incision. The patient himself rendered good service in wiping away the blood, and in holding the mucous and cutaneous surfaces together while the sutures were inserted. The hæmorrhage was very slight until sensation returned, which was not until the last suture was being put in. The patient remarked at that time that that was the first pain he had felt. The operation occupied thirteen minutes.—*The Medical Record*, February 27, 1886.

HYPONE AS AN ADJUVANT TO CHLOROFORM.—M. DUBOIS (*Revue Medicale Française et Etrangere*, Jan. 16, 1886,) states that, when a hypodermic injection of a sixth of a grain of hypnone has been given to a dog, the animal can be anæsthetized by making it breathe air containing four per cent. of chloroform, a mixture which, as M. Paul Bert has shown, never produces anæsthesia under ordinary circumstances. The anæsthesia ceases in about an hour, although the dog may continue to breathe the mixed gases. The same result may be produced by giving twice the amount of hypnone by the mouth. The practical value of these facts lies in the probable diminution that can be made in the amount of chloroform required for anæsthetization.—*The New York Medical Journal*, February 6th, 1886.

ARTIFICIAL COCAINE.—MERK succeeded in transforming benzoyl-ecgonin, a new substance discovered by him, into cocaine, as reported by the *Pharm. Zeitung* of October 31, 1885. It might interest some of the more speculative minds to know how to prepare the costly alkaloid without the Peruvian plant.

Several grammes of benzoyl ecgonin are heated to 100° (C.) with iodide of methyl and methylic alcohol, and then slowly evaporated. The product is a hydrate of iodine, and conforms to all tests of genuine cocaine, and even has the same melting-point as the latter (98°).—*Therapeutic Gazette*, January 15, 1885.

SUBCUTANEOUS INJECTION OF OXIDES OF MERCURY.—Subcutaneous injections of the black and red oxides of mercury have been recently tried as an anti-syphilitic treatment in the Lazarus Hospital at Warsaw by DR. VON WATRASZEWSKI, who has charge of the syphilitic wards. He finds that no inflammation and scarcely any pain is produced, no abscess having occurred after any of the 200 injections he has performed. The therapeutic results were most satisfactory both in recent cases and in those where the disease was of old standing.—*The Lancet*, February 13, 1885.

THE AMERICAN MEDICAL ASSOCIATION—IS IT DESIRABLE TO MAKE MATERIAL CHANGES IN THE PLAN OF ITS ORGANIZATION, PARTICULARLY IN THE DIRECTION OF ASSIMILATING IT TO THAT OF THE BRITISH ASSOCIATION WITH BRANCHES?

To increase the incentives to the formation of local medical societies and their active support by all intelligent physicians, the actual experience gained in the history of the progress of the American Medical Association not only led to an amendment of the constitution of that organization, by which the reception of delegates was restricted to State Medical Societies and such city, county and district societies as were recognized by their respective State Societies, as explained in our remarks in the preceding number of The Journal, but the same influence led to further changes in the same direction The original constitution permitted the Association at any regular meeting to elect an indefinite number of Permanent Members, provided those nominated received a unanimous vote It required but few years to show that at almost every annual meeting members were thus elected who had taken no interest in the local societies of their own city or State, and the number of these so increased as to attract attention, and led to the addition to the clause of the constitution defining the eligibility of candidates for membership, of the following clause "Nor shall any person *not a member* and *supporter* of a *local medical society*, where such a one exists, be eligible to membership in the American Medical Association" Consequently the election of Permanent Members by unanimous vote has nearly ceased

It is thus seen that simple practical experience has demonstrated during the past forty years the correctness and adequacy of the principle of strict *representation* for the support of the National Organization, while the same experience has equally shown that the few minor deviations from that principle which were incorporated into the original plan of the Association, have been steadily undergoing elimination for the sole purpose of strengthening the State and local society organizations It is an important law of social science that cannot be too clearly comprehended by all who are interested in organizing and sustaining societies of of any kind among men, that every step higher or more honorable a man gains, tends to make him more indifferent regarding the steps below An attorney who has fairly gained access to the Bar of the Supreme Court will rarely be seen doing business in a Justice court A statesman who has once sat in the legislative halls of the Nation will rarely be induced to subsequently accept a seat in the Legislature of a State or Province And as membership in a National Association is in the nature of things regarded as more honorable than one in a State Society, and the latter more so than one in a county or town society, membership in the first will make the latter seem less important, and it will be more readily neglected

Another law equally discernible in the working of human society, and the recognition of which is equally important to those who would plan wisely, is that whenever a high or desirable position is accessible through different channels, the great majority of men will take that route which is the shortest and least expensive in time or money We have already given illustrations of this in the preceding issue of The Journal, in the readiness with which the faculties of medical colleges and the staffs of hospitals, etc, sent delegates direct to the National Association, while but few of them, comparatively, were taking any part in the local societies around them until the constitution was changed But as delegates are still admitted to the National Association from city and county societies on the same basis as from the State Societies, every annual election of such delegates in the local societies results in the election of many who seldom or never attend the State Society Another illustration of the same principle is afforded by the number of those members of the profession, chiefly in our large cities, who make frequent visits across the Atlantic, choosing such times as will enable them to attend one or more of the important meetings of the medical societies in Europe The sanitary effects of a sea voyage, the gaining of recognition by eminent men abroad, and the popular *eclat* gained at home by the supposed advantages of foreign travel and study, combine to make such trips to those who have the means doubly attractive Hence it is not difficult to find those who have not only more frequently attended medical societies and institutions in Europe than those of their own country, but who appear to have also acquired far more familiarity with the medical men and literature of Germany than of either, as they actually exist in this country, while they are too readily accepted as *the prominent* medical men of America by those whose acquaintance they so assiduously cultivate, and in turn many of them acquire the habit of giving expression to the idea that we have neither educational institutions, scientific investigations, nor really eminent medical scientific men (themselves perhaps excepted) worthy of attention in this country We by no means object to visits to the societies and institutions of other countries, or to the cultivation of foreign literature, but we regard it as the duty of every right-minded man not only to thoroughly acquaint himself with the literature and institutions of his own country and ever be ready to represent them fairly, but every member of the medical profession who can command the time and means to gather knowledge in other countries, is under unusual obligations to attend and give active support to the social and scientific interests of his profession at home

The influence which has been exerted through the organization of the American Medical Association on a uniform basis of representation by delegates from State and more local organizations, exacting but the one condition that all the constituent organizations should be governed by *one* Code of Medical Ethics, has led to the establishment of efficient State Medical Societies in every State and inhabited Territory in our widely extended country, nearly all of which are based on the same representative principle in regard to the more local organizations in each State And although none of these organizations are so complete as to embrace all the members of the regular profession within their limits, yet they do *collectively* embrace a large majority of regular active members of the profession in the United States of America, and the American Medical Association, as the delegated head of all these confederated societies, is the legitimate and authorized representative of the whole If those who are in the habit of disparaging and denying the extent of the actual constituencies of the Association at the present time, will take the trouble to estimate carefully the number contained in all the State, district, county and city societies entitled to representation in the National Organization, they will find that it rests to day on an actual constituency of not less than 40,000 members of the profession

If those who have so freely indulged in denunciations of this extended National Organization during the past year, and have diligently endeavored to persuade the world that its day of usefulness had passed, and the sooner it was abandoned the better, will spend a few hours in examining the record of its influence in aiding the Medical Corps of the U S Army and of the U S Navy to obtain from Congress the legal recognition of a more just and honorable official rank, in from year to year urging directly and through its constituent State and Local Societies the enactment of laws for establishing State Boards of Health and other measures for improving the sanitary condition of all our municipalities, and in lending its entire influence until probably every member of Congress had been reached and influenced in his own home by members of the Association, who are also voting members of his own constituency, in favor of the necessary appropriations for adequate fire proof buildings to preserve and protect through all coming time the magnificent Medical Library and Museum of the Surgeon-General's Office at Washington, they may possibly see in what it has, at least, aided to accomplish, some excuse for helping it to exist for further work in the same directions

PTOMAINES, LEUCOMAINES, AND MICROBES

At the meeting of the Academie de Médecine of Paris, on February 2, M Peter read a communication on this subject, in which his object was to point out the bearing of clinical observations on the discoveries of Gautier Independently of their intrinsic value, he says, these discoveries have the merit of confirming what we know of poisoning of the organism by itself, by giving a greater degree of precision to our previous knowledge It need scarcely be said that M Peter refers to Gautier's discovery of the alkaloids of decomposition, to which Selmi gave the name ptomaines He has also shown that in living animals, and by the very fact of life itself, certain analogous alkaloids are developed, to which he has given the name "leucomaines" And he has shown that in living animals certain non-crystallizable nitrogenous substances are produced, undetermined as yet, and that these are extractive matters While all three are highly poisonous, the extractive matters possess greatest toxicity

In considering these bodies, says M Peter, we naturally turn to the chemical side Here clinical experience steps in and shows that to the difference in intoxication corresponds a difference in heat; poisoning by the extractive matters produces increase in temperature, while intoxication by the animal alkaloids produces decrease in temperature; and one may see in the same organism an association or alternance of increased and lowered temperature, according as there is an association or alternance of the different poisons. But what is very interesting, and of no little importance, says M. Peter, is that the discoveries of Gautier protect us from the tyranny of the microbes. They really explain the formation of the most poisonous alkaloids and the still more poisonous extractive matters. "They show that auto infection, *spontaneous* infection of the living organism—*spontaneous*, that is to say *by itself*—that spontaneous infection, I say, of this organism by the alkaloids and extractive matters which it produces in itself because it lives, is merely a question of quantity; in other words, the living organism may poison itself by the accumulation within itself of these substances made in itself."

But how is this poisoning of the organism by itself brought about? According to M. Peter, and the idea is by no means original with him, life is an essentially relative and contingent phenomenon; it is a series of partial deaths. Health is also an entirely relative phenomenon, and just as contingent, the unstable equilibrium between good and bad. The series of partial deaths which make up life is the result of the working of the organs of animal life. When we think heat is evolved in the brain, and the material result of cerebral activity is neurine, an alkaloid improper to normal life. Muscular movement causes heat, the material result being creatinine and other alkaloids improper to normal life. In fine, all the organs which work and which, by working undergo partial destruction, make, besides these alkaloids, extractive matters. Life, then, is also only a partial and prolonged suicide; and it is easily seen how precarious is the state called "health," and how, even by the action of our own organs, disease may supervene: all that is necessary is the accumulation in our bodies of "cadaverized" materials. Such accumulation presupposes insufficient elimination, and this may take place in two very different conditions of life. Sometimes the alkaloids and extractive materials are produced in excess, the emunctories remain normal, but are momentarily insufficient for carrying off these substances as fast as they are produced. Or there may be a normal production of these substances, but the emunctories are morbidly altered or suppressed for the time being.

Having followed our author to this point it is not difficult to see the point to which he would lead us—to a belief in the spontaneous origin of disease and thorough skepticism in all sorts of microbes, especially as we know that he has long since proved, to his own satisfaction, that a microbe is an accident. He knows that typhoid fever arises spontaneously, because he has seen cases which he could not trace to any other origin. Let us suppose, he says, that a certain quantity—say 10 units—of extractive matters and alkaloids is produced in the organism of one man, and that he only eliminates 8 *per diem*; obviously in twenty days he will have 40 retained in his system, which is sufficient for intoxication and disease. Autotyphisation is the result, and the man has typhoid fever. According to this theory we must regard disease as the result of the accumulation of a certain amount of excrementitious matter; a different amount, with different proportions of each excrementitious substance, for each affection. This would certainly be a most convenient theory if we could only find out just what matters, and how much, are retained in each disease, and how they could be eliminated before the disease sets in.

Our readers are now prepared to know that Prof. Peter holds that uræmia is due to the "adulteration of the blood by a cadaverized animal matter, the urine." In his opinion other diseases are produced in analogous ways. He concludes his remarkable paper with a denunciation of Koch and the comma-bacillus, and unhesitatingly pins his faith to Gautier's leucomaines. "Henceforth," he says, "medical intelligence will not hesitate between the parasitic doctrine, full of dark hypotheses, and this new doctrine, as luminous as precise, which explains the normal and abnormal phenomena of life by life itself in action." M. Peter's theory (or doctrine) may be compared to that so ingeniously elaborated by Desprès regarding the nature of syphilis. Both show that while a man may be an accurate and acute observer, he may be a very bad interpreter of the facts observed.

SIR ANDREW CLARK'S VIEW OF THE PATHOLOGY OF ASTHMA

In one aspect of the case it is amusing to note the great diversity of opinion among medical authorities concerning the nature of diseases; in another it is lamentable. It reveals the limitations imposed upon man's knowledge, and above all it emphasises the uncertainty of medical knowledge. There is scarcely a subject about which a difference of opinion does not prevail. As set forth in a leading article of the issue of this JOURNAL, of September 19, 1885, the etiology of asthma is no exception to the rule. With regard to this distressing malady the determination of its exact nature would have a practical bearing upon its treatment

Whatever may be said of our English brethren as pathologists, they are practical men and careful clinical observers Hence it may be of interest to know what so eminent a teacher as Sir Andrew Clark has to say on the subject of the causation of asthma The last number of the *American Journal of the Medical Sciences* contains a paper by him entitled "Some Observations on the Theory of Bronchial Asthma viewed in the light of the Pathology of Hay Fever" After setting forth his reasons for the belief that hay fever is not to be regarded as due exclusively to some external irritant, as the pollen of plants, but that there is a neurosal element in the disease, and after citing instances in which hay fever and typical spasmodic asthma alternated with each other, "like a regular see-saw between the nasal and bronchial troubles" he states certain propositions, as follows

"1 Asthma is a neuro vascular trophic disease, and has its roots in a special vulnerability of the respiratory mucous membrane, of the respiratory nerve centres, and of certain portions of the sympathetic

"2 The irritation exciting the nerve discharges which bring about the asthmatic paroxysm may arise in the blood, in any one of the mucous tracts, but more particularly the respiratory one, in certain cutaneous inflammations, and in the central nervous system itself

"3 The paroxysm begins by a more or less diffused hyperæmic swelling of the bronchial mucous membrane, and is continued by the development at various parts thereon of circumscribed congestive swellings, which come and go with greater or less rapidity, and resemble, in many particulars, the swelling of the skin in nettle rash

"4 At their first appearance these swellings become coated with a viscid mucus, hinder the entrance and exit of air, and by their vibration produce for the most part the drier râles characteristic of a certain state of the asthmatic paroxysm Towards the close of an attack, the swellings after free secretion subside, the dyspnœa is relieved, and moist takes the place of dry râles

"5 The secretion from the swellings being sometimes acrid, and even corrosive, may excite some contraction of the bronchial muscles, but such contraction can not become, either by its nature or its amount, the chief factor in the evolution of the asthmatic paroxysm

"6 The hyperæmia and circumscribed swellings of the bronchial mucous membrane hindering the free entrance of air, and thereby the full aeration of the blood, both the peripheral nerves and the respiratory centres are irritated, and exaggerated discharges of respiratory impulses are sent to the inspiratory muscles, which are thrown thereby into violent and sometimes even tetanic contractions

"7 These violent inspiratory efforts increasing the Hallerian extension force of the thoracic walls, straighten the bronchial tubes, and notwithstanding the tendency of respiratory forces to increase the size of the swellings, make the entrance of air into the lungs far easier than its exit

"8 When the inspiratory efforts cease, and the expiratory recoil begins and is continued by the muscles of forced expiration, the smaller bronchi, more especially those containing mucous wheals, are compressed, and all the passages are relaxed and lose their straight direction Thus the egress of air is greatly hindered, and the act of expiration so much prolonged that it is something suddenly interrupted and prematurely closed by the violent inspiratory efforts originated in the respiratory nerve centres through the circulation of imperfectly oxidated and decarbonized blood In this way inspiration gains upon the expiration, the alveoli are extended with air, the diaphragm is depressed, the chest, in all its dimensions, is dilated, breathing becomes more and more difficult, death seems imminent, and the paroxism is at its height

"9 After a time, varying greatly in duration, the attack begins to subside, and, partly by secretion from the bronchial mucosa, partly from the exhaustion of the excitability of the respiratory and vaso motor centres, respiration becomes easy, lividity and swelling of the face disappear, restless anxiety is displaced by growing calm, and the attack is brought to an end"

As Sir Andrew states, his theory resembles somewhat that propounded in 1872 by Weber, which is that asthma is due to a fluxionary hyperæmia of the bronchial mucous membrane, but Sir Andrew Clark says that he has taught his theory for twenty years If perused attentively, it will be found to present some novel features with which issue might fairly be taken Yet, as the author says, a theory should be judged "not by its fertility or barrenness" but by its practical workings Viewed in this light there are certainly some cases of asthma which are so amenable to treatment of the kind likely to remove bronchial congestion, if it exist, that it seems legitimate to refer the paroxysm to such a cause On the other hand, there are asthmatic patients in whom the neurotic element is so predominant as to make Sir Andrew Clark's theory inadequate to their satisfactory explanation

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, February 15th, 1886

THE PRESIDENT, C T PARKES, M D, IN THE CHAIR

(*Concluded from page 245*)

DR HENRY T BYFORD read a paper on the

PRODUCTION AND PREVENTION OF LACERATION OF THE PERINÆUM, WITH DESCRIPTION OF AN UNRECOGNIZED FORM

(See page 253)

For the purpose of illustration the perineum was divided into two parts, the vulval or external, and the vaginal or internal The former lies external to the muscles and the latter includes all the rest When the perineum is slightly stretched by the head two rings may be felt by hooking the finger over the fourchette, an external ring marking the edge of the vulva and an internal ring marking the edge of the muscles and fascia about the vaginal orifice Upon the positions and relations of these rings depends the safety of the perineum When the occiput engages in them before the forehead passes the coccyx, the fourchette and muscular edge are pressed downwards and the perineum but little bulged and not at all endangered When the occiput does not engage in the rings before the forehead leaves the coccyx, the fourchette is pushed upward before it, the perineum stretched from three to four inches antero posteriorly, while part of the propelling force and nearly all of the directing force are lost before the head passes the rings and is born The head in such cases has a greater distance to travel before delivery, involving loss of time and strength

The author described an obscure but not infrequent form of rupture in which separate muscular fibres and portions of the fascia give way all through the perineum, or through a region of it, without involving skin or mucous membrane Frequently there were not enough unruptured fibres left of the tissues to insure contraction and involution, and thus prevent displacements of the uterus A persistent flabbiness is the chief diagnostic sign To prevent rupture Dr Byford advised 1 To gain time for dilatation without injury to the deeper tissues by favoring a slow advance of the head over the floor of the pelvis 2 In order to secure sufficient dilatation of the vulval and vaginal rings to make the occiput ride over them instead of hooking under them by keeping the membranous pouch intact, or in its absence early resort to artificial dilatation rather than wait for the fourchette to be thus hooked up over a bulging perineum, and then resort to the ordinary methods

DR G H RANDALL thought that by directing the head many perineums might be prevented from rupturing We sometimes fail to direct the head and manipulate the perineum as each case requires because the woman is not in the proper position Formerly he had delivered most of his cases in the dorsal position, but not being satisfied with the way he was able to manipulate the perineum and head, he had tried the lateral position, and it seemed a great improvement He could now support the perineum by directing the head with a great deal more ease and effect than ever before, and it seemed to him that the lateral position is preferable to the dorsal

DR C T PARKES exhibited some

SPECIMENS FROM BATTEY'S OPERATION, AND OF OVARIAN TUMOR WITH TWISTED PEDICLE

"The specimens which I have to present to you on this plate are two ovaries and forty gall stones The two ovaries were removed from a lady who had suffered for over ten years from a great deal of trouble in the pelvis They are noticeable in that the left one is very small and the right one very large In this box are forty three gall stones which I removed from a gall-bladder yesterday In reference to the oophorectomy, I desire to call attention to the knot used in securing the pedicle and which has been rendered famous by Mr Tait, he calls it the Staffordshire knot Its use got me into trouble It does not secure the pedicle by merely tying the knot It must be drawn sufficiently tight to cut off circulation in the pedicle before the final knot is secured, otherwise the pedicle is very feebly constricted I used it in this case in securing the left ovary, and passed on to the removal of the right ovary, during which operation I noticed that a good deal of bleeding was going on Having removed the right ovary, I then looked for the point of hæmorrhage and found a spurting artery in the unsecured left pedicle I was astonished, because I thought I had tied the knot very tightly It is necessary that the constriction should be made by the string, and the circulation must be entirely cut off before any attempt at tying is made The other specimen is a large tumor, the weight of which was estimated at twenty-three pounds Eight days before the operation, the patient having been in a previous condition of apparent good health, was suddenly taken sick, temperature 102, pulse very fast and feeble, abdomen tender from peritonitis, urine suppressed I diagnosed a twisted pedicle, and advised immediate operation The operation was done as soon as possible, and although she was in a very feeble condition at the time, the operation apparently made very little impression up on her As soon as the abdominal incision was made a black tumor presented, and instead of the cyst portion being uppermost, as is almost invariably found, the solid portion was in front When the trocar was pulled out there was scarcely any hæmorrhage from the opening made by it, usually there is considerable hæmorrhage, especially when introduced into a solid tumor When it was removed from the abdomen there was found to be a turn and a half in the pedicle The temperature fell after the operation and did not again come up to one hundred On the seventh day all the stitches were removed and the patient is practically well to day These tumors sometimes have pedicles twisted completely off, so that they are in a sloughing condition, in other cases the twisting goes on so slowly that the pedicle is finally destroyed entirely Spencer Wells says that he has found tumors with no pedicles The three points that seem to me to indicate this diagnosis are the rapid occurrence of distension, the commencement of peritonitis, and the suppression of urine "

THE PRESIDENT said in answer to a question, that because a patient has symptoms of gall-stones and the evidences are pretty positive of their presence, no one must imagine that thereby he is going to have an easy time of the operation The case from which these gall-stones were removed was a very difficult one for operation The patient was a woman of considerable adipose tissue on the surface of the body, and it was difficult to expose the gall-bladder at all The liver, instead of being distended and projected below the ribs, was contracted and high above them It was difficult to find the gall bladder at first, and it was found to be about the size of a finger, elongated and lying in its natural position and adherent to the liver The fundus was contracted and hardened or thickened so that the finger had to be passed well down along its surface before any evidence of the stones could be found at all, it was separated from its attachments to the under surface of the liver, and then by carrying a thread through its fundus it was lifted to the top part of the incision and the finger introduced into the cavity of the gall-bladder and the stones removed Of these stones the largest was found in the gall duct It was forced from the gall duct into the gall bladder

DR H P MERRIMAN asked the President if any cause was known for the twisting of the pedicle in ovarian tumor

THE PRESIDENT said that he made very close inquiry on that point, the night previous to the occurrence of the trouble the patient felt something move in the abdomen from the left to the right side She was lying in bed at the time In reply to Dr Strong the President said he did not think that rupture of the cyst would not be followed by an increase in the size of the abdomen, nor by any change in the function of the kidney

DR W FRANKLIN COLEMAN read a paper on

A REPORT OF THREE CASES OF OSSIFICATION OF THE CHOROID, AND THE REPORT OF ONE CASE OF OSSIFICATION OF THE LENS, WITH SPECIMENS

In cases one, two, three and four the eye had been lost five, twelve, fourteen and thirty four years respectively before medical advice was sought on account of sympathetic trouble in the fellow eye In cases one, two and four the lost eye had occasionally been painful In cases one, two, three and four sympathetic disease did not occur after the loss of the eye until five, twelve, eleven and eighteen years respectively The sympathetic disease excited in case one was serous kerato iritis, case two, cyclitis, case three, irido cyclitis and cataract, case four, optic neuritis and mild iritis Dr Coleman advised the immediate enucleation of a bony eye on the same ground that the enucleation of an eye lost from injury in the ciliary region would be advised Neither the ossification nor the injury is in itself the immediate cause of the sympathetic disease, but either may be the indirect cause by exciting an irido cyclitis

DR R TILLEY said the term ossification of the lens might lead to a misunderstanding, that there is actually ever an ossification of the lens Becker, of Heidelberg, claims that ossification of the lens can not and does not take place, and that there is no case of it on record He says that in the case of a ruptured capsule a membrane may be developed from the ciliary region, and from the developing blood vessels an ossification may take place in the region of the lens, but that it should not be called an ossification of the lens He gives an interesting case showing how readily a mistake may be made and ossification supposed A boy was struck in the eye with a hay fork, and came under his care about ten hours after the accident Forty-three hours after the accident the eye was enucleated, and he thought from a macroscopic examination that the lens was intact, but on microscopic examination, what he supposed to be the lens was found to be an extravasation of blood, and the lens had escaped He remarked that it is easy to see that an ossification might have occurred, under these circumstances, and the same been taken for the lens

DR COLEMAN said, in conclusion, that he was well aware that literally and truly the lens fibres do not become ossified, but wherever connective tissue exists ossification may occur, and connective tissue may occupy the site of the lens Dr Voorhies cites a case in his own practice of an ossific mass occupying the normal position of the lens which an expert microscopist, upon examination, pronounced ossification of the lens Dr Knapp does not say he denies the possibility of such ossification

---

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 10, 1886

THE PRESIDENT, C H A KLEINSCHMIDT, M D, IN THE CHAIR

T E MCARDLE, M D, SECRETARY

THE PRESIDENT presented a

PAPILLOMA OF THE UVULA

The patient was an old gentleman between sixty and seventy years of age, a local preacher by profession He had found for several years that after preaching for twenty minutes or more he was constantly compelled to clear his throat, and before his sermon was finished his voice failed him Dr Kleinschmidt examined his throat and discovered a growth in the left side of the uvula, near the apex The tumor was removed without any difficulty Dr W W Johnston presented a similar specimen to this Society ten or fifteen years ago

DR E CARROLL MORGAN said he was glad Dr Kleinschmidt had presented this case of papilloma of the uvula to the Society, as such growths rarely develop in this location, and it consequently presents interesting features He had noticed recently in reading the report of an institution for the treatment of diseases of the throat, embracing nearly three thousand patients, that only one case of a papillomatous tumor of the pharynx was recorded, and none of the uvula proper His personal experience with papillomata of the uvula included three cases, all occurring in subjects under six years of age, one in a babe about thirteen months old The tumors in his own cases were in every instance smaller than the specimen exhibited by Dr Kleinschmidt, were readily removed, and no recurrence has taken place Dr Morgan thought that papillary growths of the uvula are often of congenital origin, and his belief is further strengthened by the tender age of his own patients and that of other recorded examples These tumors rarely attain enormous dimensions and are only occasionally observed in adults, for the annoying symptoms produced by the presence of a growth on the uvula force the patient to seek medical aid, and an early removal is the result Instances of immense papillomata of the uvula and of the pharynx are, however, reported by Lennox Browne, of London, and Roe, of Rochester In Browne's case the tumor was as large as a marble The treatment of this class of tumors is simple, requiring their removal by means of scissors, snare, or forceps, and the subsequent application of the galvano cautery blade, chromic acid, mono chlor acetic acid, or the acid nitrate of mercury, to their base Recurrences seldom, if ever, occur

Dr J B Hamilton presented some

SPECIMENS FROM A CASE OF CARIES OF THE KNEE JOINT,

upon which he had operated at Providence Hospital two weeks ago The patient was a negro who had suffered from suppuration of the knee joint for more than two years Dr Hamilton removed the patella and the joint surfaces of the femur and tibia These bones were brought in apposition, and although there is some suppuration the patient is comparatively free from pain and is doing well The specimens showed a deep abscess of the head of the tibia, and the entire joint surfaces were eroded

(*To be concluded*)

FOREIGN CORRESPONDENCE

LETTER FROM PARIS

(FROM OUR OWN CORRESPONDENT)

The Relation of Experimental Physiology to Medical Jurisprudence—Poisoning by Colchicine—Antiseptic Value of Biniodide of Mercury—Ferrán on the Comma bacillus—Medical Students in Paris—Death of Dr Daniel MacCarthy

In certain cases experimental physiology may render great service to medical jurisprudence, when chemistry so often fails According to Dr Laborde, Chef of the Physiological Laboratory of the Faculty of Medicine of Paris, it is sufficient to know how a toxic alkaloid acts upon a certain function At a recent meeting of the Société de Biologie, Dr Laborde developed the subject in the following example A dóg was accidentally poisoned in a laboratory, presumably by veratria or by aconitine Chemistry was inefficient to solve the problem by the examination of the different organs and the liquids they contained It was then determined that a certain quantity of these liquids should be injected into the cellular tissue of a dog that was procured for the experiment, the beats of the heart were modified and the graphic tracings indicated in a *peremptory* manner that it was aconitine that was the substance absorbed, which, however, existed in too small quantity for chemical reagents to detect By physiological experiment one can obtain more precise results, and be able to know, exactly, the dose of the poison absorbed

This mode of investigation, however, does not seem to answer in all cases In a report read by Professor Brouardel at a recent meeting of the Société de Médecine Légale, on a case of *poisoning by colchicine*, he stated that fragments of the viscera of the supposed victim which were injected into the veins of animals, produced no phenomena characteristic of poisoning by colchicine. Moreover, the author observed that to establish a case of poisoning there must be perfect concordance between the points of information furnished 1 By chemical examination, 2 by the necropsy, 3 by chemical analysis, 4 by physiological experiments In the case under consideration, the hypothesis of poisoning by colchicine was justified by the symptoms observed during life, which clinical information might be added to the conditions named above, as being necessary for the elucidation of cases of reputed poisoning

M Miguel, a well known chemist, in a list published by him of the antiseptic power of divers substances, placed the bichloride of mercury among the most efficient, but it has since been superseded by the biniodide of mercury, which, after some new experiments by the author, has been found three times more active than the bichloride To prevent fermentation in a litre of sterilized bouillon, it requires about 25 milligrammes of the biniodide of mercury and 70 milligrammes of the bichloride It is impossible for bacteria to live in a solution of the biniodide of mercury of the strength of $\frac{10}{1000}$, or of the bichloride of that of $\frac{14}{1000}$ The author recommends that when a good antiseptic is required, whether in obstetrics or whether after operations on the vagina and the uterus, a solution of the biniodide of mercury of the strength of $\frac{1}{4000}$th should be employed in preference

After having retired in obscurity for awhile, Dr Ferrán, the famous anti cholera vaccinator, has revived his favorite subject by addressing to the Paris Academy of Sciences a work got up by him in conjunction with M J Pauli, "On the Active Principle of the Comma bacillus, as the Cause of Death and of Immunity" From four series of experiments performed on guinea pigs, the authors drew the following conclusions 1 The dead comma bacillus communicates the tolerance which permits the organism to resist the effects of the living comma-bacillus 2 The active principle of the comma bacillus, isolated by certain known methods, confer a condition which permits the organism to resist the effects of the living microbe, and vice versa According to MM Ferrán and Pauli, the cause which determines immunity and that which occasions death are one and the same, and is essentially of a chemical nature, consequently immunity is in reality nothing more than a certain habit or state of the system which may be obtained by purely chemical agents

In his report for the past year, Dr Béclard, the Dean of the Faculty of Paris, makes the following statement The average number of students has been about the same as that for the last few years, viz, 4000 Of this number there were 103 women, among whom there was one Indian, one Turk, three Austrians, eight French, and seventy-six Russians During the last seven years only eighteen diplomas were issued to doctoresses, rather a small number in proportion to the number of lady students who took out their inscriptions Dr Béclard further states that the presence of women among the students has, till now, caused no inconvenience in a disciplinarian or moral point of view Four hundred and eighty degrees of Doctor of Medicine were given to candidates of both sexes during the year

At the last competitive examination for the Externat of the Paris Hospitals there were 287 candidates, and among the successful ones I find the names of four lady students, Miss Klumpke took the ninth place in the list At the examination for the Internat, at which ninety-eight candidates were received, Miss Klumpke came out the twelfth

The English Colony in Paris has just lost one of its oldest and most respected members by the death of Dr Daniel MacCarthy, at the age of 69 years He had been in failing health for some months past, in consequence of which he had been gradually obliged to relinquish his large practice The deceased physician was the son of English parents, but he had spent the greater part of his life in France, which became the country of his adoption He took his degree in 1844 at the Paris Faculty of Medicine, and although his connections were principally French, his practice extended to the English speaking residents of Paris A B

DOMESTIC CORRESPONDENCE

BRANCHES OF THE AMERICAN MEDICAL ASSOCIATION

To THE EDITOR OF THE JOURNAL

Dear Sir —From the tone of the letters published in THE JOURNAL of February 27, especially those of Drs Hamilton and Keller, I am afraid that I did not state my ideas on this subject with sufficient clearness in my letter in THE JOURNAL of February 6 My whole object is the future good of the Association, *and therefore* of the medical profession in this country My object is *not* so much to increase the *power* of the Association, as its influence, and the further object is to organize the profession in America Dr Hamilton and some others seem to be under the impression that it was proposed to do away with the State Societies and their power altogether On the contrary, I took special pains, in my letter of Feb 6th, to keep any one from thinking that I advocated such absurdity Dr Hamilton's proposition to "simply open the doors of the Association so that its members shall include the members of affiliated State Medical Societies," etc, must be regarded, I think, as excellent

Dr Keller also seems to have mistaken my meaning when he says "I can see no other object in making the changes suggested than that of increasing our membership and strengthening or replenishing our treasury, at the sacrifice of our State Societies, which have done good work in standing as the only gates through which entrance to the Association could possibly be effected, and it occurs to me that the moment they are removed we will let down the bars to hordes of crooks and charlatans whose crookedness shuts them out of Societies at home where they are best known" I cannot see how my meaning could possibly have been so mistaken In THE JOURNAL of February 6, page 164, I say expressly "The State Society would still have control of its members" There is not a word in the whole letter which advocates sacrificing the State Societies, and not a word which can be construed to mean that the Branch system would let down a single bar to a charlatan The safeguards against crooks and charlatans would be as strong as ever, but a very large amount of red tape would be taken away from the requirements for admission to the Association when *respectable and reputable physicians* desire to enter The British Association has members who are not attached to any Branch, and the American Association has members who are not members of any State or local Society, but they are not necessarily charlatans But I hope that those who enter into this discussion in the future will at once read my letter carefully, and dispossess their minds of the idea that there is a plan on foot to relegate the State Societies to the limbo of oblivion I would have them stay just where they are, as regards all their rights and privileges The object of my proposition undoubtedly is to increase the membership of the American Medical Association, to make it more powerful for good and against evil in the profession If any one can propose a plan which will be more acceptable to the majority than the Branch system, I will certainly not raise my voice against it, but I do not see that a plan is necessarily bad because it is imported from Europe (and I am not an Anglo maniac) The plan suggested by Dr Hamilton certainly has the merit of simplicity

Finally, the differences of opinion shown in the four letters published in THE JOURNAL of February 27, shows that the subject has not been broached any too soon, for the whole matter should be brought up before the meeting in St Louis, and referred to a committee to report on at the annual meeting in 1887 And while any plan would be objectionable which would sacrifice existing organizations, a plan which would ignore them would be equally objectionable

Inasmuch as the adoption of any one of the plans proposed would necessitate a change in the Constitution of the Association, and as any proposed change must lie over for one year, the whole matter should be referred to a wisely selected committee, which should fully investigate the matter in all its bearings and aspects, obtaining, in so far as possible, the sentiment of members of State and local Societies, so as to make a complete and comprehensive report in 1887 BRANCH

TO THE EDITOR OF THE JOURNAL

Dear Sir —In a letter in THE JOURNAL of February 6, "Branch" opens up a very proper field of discussion in the closing paragraph of his letter on "Branches of the American Medical Association," when he says "Any one who will take the trouble to look the matter up will be surprised to see the number of physicians in this country who do not belong to any medical organization at all Even in some of the most populous States there are numbers of Counties without any medical society, and in many of the Counties in which medical societies exist, there are numbers of medical men who have no connection with them "

To show that this is true I need only mention the State of Illinois as a most striking example Exclusive of Cook County there are one hundred Counties in the State, with only *seventeen* (?) County Medical Societies These one hundred Counties have between 3400 and 3500 regular physicians, and only 417 who are members of a County Medical Society As regards the proportion of society members in the Counties in which societies exist, the following are the figures, as nearly as I can ascertain Adams County, 87 regular physicians and 48 Society members, Champaign, 76 physicians and 27 members, Clinton, 28 to 9, Crawford, 29 to 11, De Witt, 32 to 20, Douglass, 31 to 19, Jersey, 17 to 6, Macoupin, 56 to 32, Madison, 67 to 26, McLean, 83 to 57, Montgomery, 36 to 13, Ogle, 33 to 16, St Clair, 79 to 27, Stephenson, 36 to 19, Vermillion, 80 to 43, Winnebago, 51 to 22, and Woodford, 23 to 22 Seventeen Counties, therefore, with 844 regular physicians, have only 417 society members (this is as near as I can approximate without late returns) There are 911 regular physicians in Cook County, 812 of whom are in the city of Chicago Of the 99 outside of the city 8 are members of the County Medical Society, 6 are members of the State Medical Society (2 of whom are members of the County Medical Society), and 3 are members of the American Medical Association There are, then, 87 regular physicians in Cook County, outside of the city who are not members of any medical organization Of the 812 in the city only 302 are members of the County Medical Society As the transactions of the Illinois State Medical Society for 1885 has not yet been published I have not been able to ascertain the number of members in the State Society, but I may safely say that there are not 1000 members From the "Medical Directory" it appears that only 96 of the 812 in the city are members of the State Society

It must be admitted that this is an exceedingly poor showing It may not be worse than that in some other States, but at the same time it is bad It shows that there must be something radically wrong with the societies or with the doctors—and we can scarcely believe that the great majority of our medical men are at fault In order to join the British Association or one of its Branches the candidate must be recommended as eligible by three members, and he may be elected a member by the *General Council* of the Association, or by any recognized *Branch Council* (the name of the candidate seeking election by a Branch Council must be inserted in the circular calling the meeting at which he seeks election) Red tape is thus reduced to a minimum, and yet there is no more probability of a bad man getting in than into one of our State Societies It seems absurd to keep a man out of a State Society—or out of the American Medical Association (as was the case before the meeting in 1884)—because he does not or can not attend the annual meeting at which he seeks election In 1885 my name was placed before the Chicago Medical Society for two reasons I wished to be a member of the local Society, and I was anxious to join the State Society at the Springfield meeting I was told that there would be no difficulty in being sent as a delegate from the Chicago Medical Society There was no want of time, for the State Society was not to meet for about six or eight weeks After my name got into the hands of the Committee and before the Society, the business of the Society hung fire, meeting after meeting, in order that some quarrel might be "investigated" The result was that my name, and those of several other applicants for membership, remained unacted upon, and I could not join the State Society

In many respects the "delegate system" is simply a nuisance, a seemingly nicely devised plan for keeping out men who cannot attend a meeting or who are not members of a local society And when, as is the case in Illinois in so many counties, there is no County Medical Society, hundreds and hundreds of physicians may be kept out of the State Society altogether Having heard that the "delegate system" is not in force in the Medical Society of Virginia, I find the following regulation for the admission of members in the Constitution of that Society "Every candidate for Fellowship shall make application to the Committee on Nominations, such application to be presented and endorsed by a Fellow having a competent knowledge of the applicant If this Committee shall report favorably thereon to the Society, the candidate shall be balloted for, and the approving votes of three fourths of the Fellows present shall be necessary to his admission " The application must be accompanied by the initiation fee, which is returned if the candidate be not elected In the *Transactions* of that Society for 1885 I find that 105 new members were thus elected at the last annual meeting Now, if this method of electing members of the State Society is successful in Virginia, why should it not also succeed in Illinois and other States, and in the American Medical Association? It may be said that it is not so desirable to increase the membership of the Societies as to get *good* men into them I do not believe in the "holier than thou" sentiment The Societies are for all reputable phymicrobe, and vice versa According to MM Ferrán and Pauli, the cause which determines immunity and that which occasions death are one and the same, and is essentially of a chemical nature, consequently immunity is in reality nothing more than a certain habit or state of the system which may be obtained by purely chemical agents

In his report for the past year, Dr Béclard, the Dean of the Faculty of Paris, makes the following statement The average number of students has been about the same as that for the last few years, viz, 4000 Of this number there were 103 women, among whom there was one Indian, one Turk, three Austrians, eight French, and seventy-six Russians During the last seven years only eighteen diplomas were issued to doctoresses, rather a small number in proportion to the number of lady students who took out their inscriptions Dr Béclard further states that the presence of women among the students has, till now, caused no inconvenience in a disciplinarian or moral point of view Four hundred and eighty degrees of Doctor of Medicine were given to candidates of both sexes during the year

At the last competitive examination for the Externat of the Paris Hospitals there were 287 candidates, and among the successful ones I find the names of four lady students, Miss Klumpke took the ninth place in the list At the examination for the Internat, at which ninety-eight candidates were received, Miss Klumpke came out the twelfth

The English Colony in Paris has just lost one of its oldest and most respected members by the death of Dr Daniel MacCarthy, at the age of 69 years He had been in failing health for some months past, in consequence of which he had been gradually obliged to relinquish his large practice The deceased physician was the son of English parents, but he had spent the greater part of his life in France, which became the country of his adoption He took his degree in 1844 at the Paris Faculty of Medicine, and although his connections were principally French, his practice extended to the English speaking residents of Paris A B

DOMESTIC CORRESPONDENCE

BRANCHES OF THE AMERICAN MEDICAL ASSOCIATION

To the Editor of the Journal

Dear Sir —From the tone of the letters published in The Journal of February 27, especially those of Drs Hamilton and Keller, I am afraid that I did not state my ideas on this subject with sufficient clearness in my letter in The Journal of February 6 My whole object is the future good of the Association, *and therefore* of the medical profession in this country My object is *not* so much to increase the *power* of the Association, as its influence, and the further object is to organize the profession in America Dr Hamilton and some others seem to be under the impression that it was proposed to do away with the State Societies and their power altogether On the contrary, I took special pains, in my letter of Feb 6th, to keep any one from thinking that I advocated such absurdity Dr Hamilton's proposition to "simply open the doors of the Association so that its members shall include the members of affiliated State Medical Societies," etc, must be regarded, I think, as excellent

Dr Keller also seems to have mistaken my meaning when he says "I can see no other object in making the changes suggested than that of increasing our membership and strengthening or replenishing our treasury, at the sacrifice of our State Societies, which have done good work in standing as the only gates through which entrance to the Association could possibly be effected, and it occurs to me that the moment they are removed we will let down the bars to hordes of crooks and charlatans whose crookedness shuts them out of Societies at home where they are best known" I cannot see how my meaning could possibly have been so mistaken In The Journal of February 6, page 164, I say expressly "The State Society would still have control of its members" There is not a word in the whole letter which advocates sacrificing the State Societies, and not a word which can be construed to mean that the Branch system would let down a single bar to a charlatan The safeguards against crooks and charlatans would be as strong as ever, but a very large amount of red tape would be taken away from the requirements for admission to the Association when *respectable and reputable physicians* desire to enter The British Association has members who are not attached to any Branch, and the American Association has members who are not members of any State or local Society, but they are not necessarily charlatans But I hope that those who enter into this discussion in the future will at once read my letter carefully, and dispossess their minds of the idea that there is a plan on foot to relegate the State Societies to the limbo of oblivion I would have them stay just where they are, as regards all their rights and privileges The object of my proposition undoubtedly is to increase the membership of the American Medical Association, to make it more powerful for good and against evil in the profession If any one can propose a plan which will be more acceptable to the majority than the Branch system, I will certainly not raise my voice against it, but I do not see that a plan is necessarily bad because it is imported from Europe (and I am not an Anglo maniac) The plan suggested by Dr Hamilton certainly has the merit of simplicity

Finally, the differences of opinion shown in the four letters published in The Journal of February 27, shows that the subject has not been broached any too soon, for the whole matter should be brought up before the meeting in St Louis, and referred to a committee to report on at the annual meeting in 1887 And while any plan would be objectionable which would sacrifice existing organizations, a plan which would ignore them would be equally objectionable

Inasmuch as the adoption of any one of the plans proposed would necessitate a change in the Constitution of the Association, and as any proposed change must lie over for one year, the whole matter should be referred to a wisely selected committee, which should fully investigate the matter in all its bearings and aspects, obtaining, in so far as possible, the sentiment of members of State and local Societies, so as to make a complete and comprehensive report in 1887. BRANCH.

To the Editor of the Journal:

Dear Sir:—In a letter in The Journal of February 6, "Branch" opens up a very proper field of discussion in the closing paragraph of his letter on "Branches of the American Medical Association," when he says: "Any one who will take the trouble to look the matter up will be surprised to see the number of physicians in this country who do not belong to any medical organization at all. Even in some of the most populous States there are numbers of Counties without any medical society, and in many of the Counties in which medical societies exist, there are numbers of medical men who have no connection with them."

To show that this is true I need only mention the State of Illinois as a most striking example. Exclusive of Cook County there are one hundred Counties in the State, with only *seventeen* (?) County Medical Societies. These one hundred Counties have between 3400 and 3500 regular physicians, and only 417 who are members of a County Medical Society. As regards the proportion of society members in the Counties in which societies exist, the following are the figures, as nearly as I can ascertain: Adams County, 87 regular physicians and 48 Society members; Champaign, 76 physicians and 27 members; Clinton, 28 to 9; Crawford, 29 to 11; De Witt, 32 to 20; Douglass, 31 to 19; Jersey, 17 to 6; Macoupin, 56 to 32; Madison, 67 to 26; McLean, 83 to 57; Montgomery, 36 to 13; Ogle, 33 to 16; St. Clair, 79 to 27; Stephenson, 36 to 19; Vermillion, 80 to 43; Winnebago, 51 to 22; and Woodford, 23 to 22. Seventeen Counties, therefore, with 844 regular physicians, have only 417 society members (this is as near as I can approximate without late returns). There are 911 regular physicians in Cook County, 812 of whom are in the city of Chicago. Of the 99 outside of the city 8 are members of the County Medical Society, 6 are members of the State Medical Society (2 of whom are members of the County Medical Society), and 3 are members of the American Medical Association. There are, then, 87 regular physicians in Cook County, outside of the city who are not members of any medical organization. Of the 812 in the city only 302 are members of the County Medical Society. As the transactions of the Illinois State Medical Society for 1885 has not yet been published I have not been able to ascertain the number of members in the State Society, but I may safely say that there are not 1000 members. From the "Medical Directory" it appears that only 96 of the 812 in the city are members of the State Society.

It must be admitted that this is an exceedingly poor showing. It may not be worse than that in some other States, but at the same time it is bad. It shows that there must be something radically wrong with the societies or with the doctors—and we can scarcely believe that the great majority of our medical men are at fault. In order to join the British Association or one of its Branches the candidate must be recommended as eligible by three members, and he may be elected a member by the *General Council* of the Association, or by any recognized *Branch Council* (the name of the candidate seeking election by a Branch Council must be inserted in the circular calling the meeting at which he seeks election). Red tape is thus reduced to a minimum, and yet there is no more probability of a bad man getting in than into one of our State Societies. It seems absurd to keep a man out of a State Society—or out of the American Medical Association (as was the case before the meeting in 1884)—because he does not or can not attend the annual meeting at which he seeks election. In 1885 my name was placed before the Chicago Medical Society for two reasons: I wished to be a member of the local Society, and I was anxious to join the State Society at the Springfield meeting. I was told that there would be no difficulty in being sent as a delegate from the Chicago Medical Society. There was no want of time, for the State Society was not to meet for about six or eight weeks. After my name got into the hands of the Committee and before the Society, the business of the Society hung fire, meeting after meeting, in order that some quarrel might be "investigated." The result was that my name, and those of several other applicants for membership, remained unacted upon, and I could not join the State Society.

In many respects the "delegate system" is simply a nuisance, a seemingly nicely devised plan for keeping out men who cannot attend a meeting or who are not members of a local society. And when, as is the case in Illinois in so many counties, there is no County Medical Society, hundreds and hundreds of physicians may be kept out of the State Society altogether. Having heard that the "delegate system" is not in force in the Medical Society of Virginia, I find the following regulation for the admission of members in the Constitution of that Society: "Every candidate for Fellowship shall make application to the Committee on Nominations, such application to be presented and endorsed by a Fellow having a competent knowledge of the applicant. If this Committee shall report favorably thereon to the Society, the candidate shall be balloted for, and the approving votes of three fourths of the Fellows present shall be necessary to his admission." The application must be accompanied by the initiation fee, which is returned if the candidate be not elected. In the *Transactions* of that Society for 1885 I find that 105 new members were thus elected at the last annual meeting. Now, if this method of electing members of the State Society is successful in Virginia, why should it not also succeed in Illinois and other States, and in the American Medical Association? It may be said that it is not so desirable to increase the membership of the Societies as to get *good* men into them. I do not believe in the "holier than thou" sentiment. The Societies are for all reputable physicians, and each should be considered reputable until he shows that he is not, when he may be easily removed This is certainly much better than keeping a man out because he *may* not be all that is desirable

In this connection may be mentioned the following propositions which the secretaries of the county societies in Ohio have been asked to bring before the societies 1 To so change the constitution of the State Society as to make the members of the county societies members of the State Society simply by virtue of their local membership 2 Present members of the State Society to remain members without reference to membership in local societies 3 All members to stand upon an equal footing, thus doing away with the delegate system Such amendments to the constitution of the Illinois State Medical Society would still exclude very many practitioners from membership

It must seem, therefore, that the question opened by "Branch," and further discussed in The Journal, of February 27, is one of vital importance to our County and State Societies, to the American Medical Association, and to the whole profession in this country, though it is to be regretted that some of the correspondents have made it appear that "Branch" advocated supplanting or sacrificing the State Societies Their letters, written with this idea, may prejudice many against the plan proposed, even were it the best, but careful reading of his letter will show that he has not advocated any such thing One thing is very certain the profession needs more efficient and more active organization than exists at present The Association is not what it should be, nor are the State and County Societies what they should be Some organization, based on the suggestions already offered by the correspondents on the Branch question will undoubtedly make them what they should be Illinois

---

To the Editor of the Journal

Dear Sir —Two admirable letters on this subject have lately appeared in The Journal, one signed "Branch," in the issue of February 6, the other from Dr James H Parkinson, of Sacramento, California, in the issue of February 27, 1886 It seems to the subscriber that the time has come when measures should be taken tending to increase the membership of our Association, and to render it in letter what it already is in spirit, the representative body of the regular medical profession of the United States of North America How to accomplish this object has been indicated by "Branch" and by Dr Parkinson

Our country is so vast that it will not be possible for members who live in distant States to attend meetings which may be held at the extreme North, South, East or West To overcome these difficulties, the subscriber asks leave to offer some suggestions as a basis for a plan of organization which, if adopted, will place the American Medical Association in the position which that body should occupy in the medical world, and, as Dr Parkinson says, enable "the profession to express itself as a unit upon vital questions"

Suggestions —1 For the purpose of fully carrying out the objects set forth above, the United States should be divided into nine geographical sections, to be known respectively as the First or Northern, the Second or Northeastern, the Third or Northwestern, the Fourth or Eastern, the Fifth or Central, the Sixth or Western, the seventh or Southern, the Eighth or Southeastern, and the Ninth or Southwestern, Division These nine Divisions should comprise all the States and Territories, and the District of Columbia, arranged as follows

First or Northern Division, including Dakota, Illinois, Indiana, Iowa, Michigan, Minnesota, Ohio, Wisconsin, 8 States

Second or Northeastern Division, comprising Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont, 9 States

Third or Northwestern Division, comprising Alaska, Idaho, Montana, Oregon, Washington, Wyoming, 6 States

Fourth or Eastern Division, comprising Delaware, District of Columbia, Kentucky, Maryland, North Carolina, Tennessee, Virginia, West Virginia, 8 States

Fifth or Central Division, comprising Colorado, Kansas, Missouri, Nebraska, 4 States

Sixth or Western Division, comprising California, Nevada, Utah, 3 States

Seventh or Southern Division, comprising Arkansas, Indian Territory, Louisiana, Mississippi, 4 States

Eighth or Southeastern Division, comprising Alabama, Florida, Georgia, South Carolina, 4 States

Ninth or Southwestern Division, comprising Arizona, New Mexico, Texas, 3 States

2 There should be established nine Branches of the American Medical Association, one in each of the geographical divisions These Branches should be known respectively as the First or Northern, the Second or Northeastern, the Third or Northwestern, the Fourth or Eastern, the Fifth or Central, the Sixth or Western, the Seventh or Southern, the Eighth or Southeastern, and the Ninth or Southwestern, Branch of the American Medical Association

3 The headquarters of each Branch Association should be in the most populous city in its geographical division

4 Each Branch Association should hold one meeting annually, and this meeting should not be held any two successive years in any one State belonging to its geographical division

5 No member of the medical profession should be a member of any Branch until he has joined the American Medical Association, the parent of all the Branches, and none should be eligible for membership to the American Medical Association who is not a member of his State Association

6 The officers of the American Medical Association should be A President, nine Vice Presidents, one from each Division, one Secretary, and nine Associate Secretaries (one from each Division), who should be stenographers, and a Treasurer

7 The Judicial Council should be composed as follows The President, the nine Vice Presidents, the Secretary, the Treasurer, two members from each

Division (eighteen), and one appointed at large by the President, making thirty one in all, who should manage the affairs of the Association.

8. The officers of the Branch Associations should be: A President (one of the nine Vice-Presidents of the American Medical Association), Vice-Presidents, who should be the Presidents of the various State Associations in the Division, a Secretary, and two Associate Secretaries (who should be stenographers). The President, Vice-Presidents, the Secretary and one member from each State, Territory or District, should constitute the Executive Committee or Council of each Branch Associattion and should manage its affairs.

9. The headquarters of the parent Association should be in the City of Washington, D. C., where there should be held, instead of the annual meetings, a triennial Congress of the American Medical Association, dividing the Congress into fifteen Sections as follows:

1. Anatomy, Physiology and Pathology.
2. Pharmacology, Botany, Materia Medica and Therapeutics.
3. General Medicine.
4. General Surgery.
5. Obstetrics.
6. Gynecology.
7. Pediatrics.
8. Hygiene, State Medicine and Climatology.
9. Chemistry, Toxicology and Forensic Medicine.
10. Ophthalmology and Otology.
11. Rhinology and Laryngology.
12. Dermatology and Syphilis.
13. Diseases of the Mind and Nervous System.
14. Medical Education, History, Literature and Journalism.
15. Dental and Oral Surgery.

10. Each Section should elect its own President, Vice Presidents, Secretaries and Council with due regard to representation from all the geographical Divisions.

In conclusion the subscriber suggests that the American Medical Association appoint at its next meeting a special committee instructed to frame a comprehensive plan of organization, preserving *intact* our excellent Code of Ethics, and all the by laws and special resolutions relating thereto.

ACTIVE MEMBER.

TO THE EDITOR OF THE JOURNAL:

Dear Sir:—A communication in your JOURNAL of February 6, over the signature "Branch," invites attention to a matter of peculiar interest to the medical profession of the country, namely: the discussion of measures that will more thoroughly bring together and cement the profession, advance the interests of medicine, and build up and strengthen the American Medical Association.

That the American Medical Association should be to the profession of the United States what the British Medical Association is to the profession of England, it would seem, should be the earnest wish of every true minded physician of this country, and the idea of establishing Branches, or of making every State Medical Society and every local medical organization a Branch, working in harmony and in consonance with the plans and rules of the American Medical Association, certainly appears well adapted to achieve this desirable object.

Whether the mass of our physicians are educated up to this advanced position or not, to make the plan a working success, admits of doubt, and perhaps, under existing circumstances, the better plan would be to utilize the State Medical Societies, making them, with the consent of their members, Branches of the American Medical Association. This plan is suggested by your correspondent, "Branch," and all the objections that might be raised to it fully answered.

There are two prominent purposes to be aimed at in any action that may be taken. *First*, To enlarge and make the American Medical Association a tower of strength, and to embrace in its membership every regular, respectable and intelligent physician in every State and Territory of the United States, making it a truly representative body of the entire medical profession, and the supreme authority upon all questions bearing upon the interests of medicine, and the professional and social deportment of its members. And, *Second*, The advancement of medical science and the collateral branches, and the elevation of the medical profession.

The Association, at its meeting in 1884, I believe, enacted a law or provision by which any member of a State or local medical society, if in good standing and vouched for, may become a "Member by Application" of the Association. This is surely a very broad provision, and in the right direction; and yet, somehow, the privilege is not understood or properly appreciated by the profession, judging from the rate of increase of membership since the provision was adopted. It seems to lack the attraction and force which attach to Branch organizations, and is wanting in that complement of professional work and responsibility which the latter would impose upon each member. Hence I regard "Branch's" suggestions opportune and good, and hope to see them fully discussed from now on, and brought before the Association at its meeting in St. Louis in next May.

MEDICUS.

Baton Rouge, La.

TO THE EDITOR OF THE JOURNAL:

Dear Sir:—I agree with "Branch" in his letter of February 6, as to the propriety of, in some way, popularizing membership in the American Medical Association. Give members of the profession a chance to join the Association. There are thousands who would willingly do so, but who cannot attend the yearly meeting, or cannot secure election as delegates. Under present rules only delegates, or those who live at the place of holding the meeting of the Association, can become members.

Our large institutions of learning are recognizing the necessity of extending facilities for students who desire to enter, by having examinations at other centres as well as where the college may be situated, thus saving to the applicant the expense and trouble of long journeys

There should be some regulation adopted by the American Medical Association, and widely published to the profession, whereby members of the medical profession can become members of the Association without presenting themselves in person for election Then, as members increase, the annual dues can be decreased In other words, make it easy to any reputable member of the medical profession to join the American Medical Association, and in this way there is every reason to believe it would number its members by the thousands

Very truly yours,
J H BAXTER, M D
Washington, D C , February 20, 1886

ACTION OF SUBCUTANEOUS INJECTIONS OF COCAINE

TO THE EDITOR OF THE JOURNAL

Dear Sir —With the view of contributing to the knowledge of the action of subcutaneous injections of cocaine, I beg leave to submit the following observations made upon myself

Having read so much of the exhilarating and enlivening actions of cocaine and of its great stimulating power upon the cerebral nervous system, I resolved to try its effects upon myself For this purpose I administered to myself, being in good health and of usual normal spirits and mental disposition, a subcutaneous injection of ½ grain of muriate of cocaine (Merck), repeating the dose after five minutes, as no effect whatever had taken place in the interval About five minutes after the last injection I felt slight dizziness in the head, a prickling sensation in the tips of my fingers, and slight pressure in the epigastrium—all of which symptoms passed off within ten minutes I was able to continue the literary work in which I was just engaged, but with some effort I labored under slight drowsiness and my limbs became heavy The action of the heart and pulsation were rather retarded The face was pale, the sensibility of the cornea normal, that of the mucous membrane of the globe slightly reduced Pupils were regular Normal condition was reestablished after half an hour of rest during which time I had full control of my mental faculties

After an interval of four days I repeated the experiment, using at once 2 grains of cocaine for hypodermatic injection Hardly had two minutes elapsed after the administration when I felt my heart beating violently and the blood rushing to the head, which was quickly followed by a sensation of fulness and roaring in the latter and by noises in the ears There was confusion of thought and impairment of the faculty of volition A feeling of great uneasiness invaded the whole body, and slight twitching movements were felt in the toes and fingers, with a sensation of numbness The feeling of nausea and pressure in the epigastrium was very marked The acme of the paroxysm lasted for over five minutes, after which I found the face very pale and covered with cold perspiration The eyeballs were somewhat sunken into the orbit, the pupils were enlarged, but of normal reflex action and accommodative power The objects appeared slightly dim, but of normal proportions Retraction and coordination of muscles were not changed The sensibility of the cornea and conjunctiva was greatly diminished Pulse was feeble, arterial tension and action of the heart slightly reduced I felt tired and worn out, unable to concentrate my thoughts or to struggle against the creeping drowsiness Half an hour after the injection I went to bed, laboring under nausea, general prostration, and slight attack of hemicrania. Sound sleep during the whole night brought about perfect recovery

THE ASSOCIATION LED ASTRAY!

TO THE EDITOR OF THE JOURNAL

Dear Sir —My attention has been called to an editorial in the *American Practitioner*, of February 20, reproduced in the *Medical News* of the 20th ult I take it for granted it was written by the senior editor, Dr D W Yandell To all those familiar with the doings of the American Medical Association this editorial will sound strangely To quote "It (the A M A) was led astray at New Orleans (Why was not Dr D W Yandell, ex President of the Association, there to keep it from being led astray?) It will doubtless be led astray again, and yet again, for designing, ambitious, selfish and industrious plotters will gather at every meeting, and opportunities for their *securing power* (italics ours) will occasionally occur " Dr D W Yandell made his first appearance as a delegate from Kentucky in 1856, then in 1857 and 1859 His name does not appear again (nor his State) till 1871, when in San Francisco he was elected President Neither his State nor he had any claims to the honor It was, so report said, due to designing, ambitious, selfish and industrious plotting that the Presidency was awarded him Since that time the senior editor of the *American Practitioner* and ex President of the American Medical Association has attended only four meetings, and since 1874 none at all With the exception of his address as President, no other contributions appear from his pen to the Association In Dr Yandell's Address (see page 103, Vol 23, Trans A M A) he says "The Association is making our profession one in heart throughout our borders" How does this comport with his ideas of 1886? He who runs can read

Does such a career entitle the ex President to read a lecture to the Association as to how it shall conduct itself? The least modicum of modesty should have taught him to *keep his say* to himself Moses did very well when he was among the people, but when he climbed the mountain to see "the promised land" his influence was gone We fear the senior editor of the *American Practitioner* was elevated too early for his years An ex-President of the Association should have some influence, and it should be in the body which has made him distinguished With many others who have known him for years we sincerely regret the position he has taken In the welfare and interest of the Association we hope to see Dr Yandell at St Louis in May next, and if his Kentucky eloquence can convince the American Medical Association that they have gone astray, we will cordially admit it We are sorry Dr Yandell has taken the course he has—we can only pity him

TRUTH

DISINFECTION OF CATHETERS

TO THE EDITOR OF THE JOURNAL

Dear Sir —Permit me in this day of "catheter fever" to offer to your readers my mode of disinfecting catheters Dr Alexander Skene says that when he cut into his catheters which had lain several days in a strong solution of carbolic acid, they still contained micrococci underneath the incrustation Taking a hint from that, I now pass through the catheter a saturated solution of iodoform in ether The ether penetrates the incrustation, carries with it the iodoform, and performs its function where liquid could not enter Yours truly,

W P SHOEMAKER, M D

Bradford, Pa , February 9, 1886

ASSOCIATION ITEMS

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo , on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By-Laws*, Article 11, Sec 4

Practice of Medicine, Materia, Medica and Physiology —Dr J T Whittaker, Cincinnati, Ohio, *Chairman*, Dr B L Coleman, Lexington, Ky , *Secretary*

Obstetrics and Diseases of Women and Children —Dr S C Gordon, Portland, Me , *Chairman*, Dr J F Y Paine, Galveston, Texas, *Secretary*

Surgery and Anatomy —Dr Nicholas Senn, Milwaukee, Wis , *Chairman*, Dr H H Mudd, St Louis, Mo , *Secretary*

State Medicine —Dr John H Rauch, Springfield, Ill , *Chairman*, Dr F E Daniel, Austin, Texas, *Secretary*

Ophthalmology, Otology, Laryngology —Dr Eugene Smith, Detroit, Mich , *Chairman*, Dr J F Fulton, St Paul, Minn , *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn , *Chairman*, Dr W B Lawrence, Batesville, Ark , *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago, Ill , *Chairman*, Dr A E Baldwin, Chicago, Ill , *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

WM B ATKINSON, M D ,
Permanent Secretary

1400 Pine St , S W cor Broad, Philadelphia

MISCELLANEOUS

MEDICAL SCHOOLS AND STUDENTS IN THE UNITED STATES —The Illinois State Board of Health has recently issued a pamphlet entitled "Medical Education and Medical Colleges in the United States and Canada, 1765–1885," in which the most suggestive facts revealed by tables and data are First, that the number of medical colleges has not increased during the past year, secondly, that the number of medical students and of medical graduates is decreasing, and thirdly, that there is a more marked uniformity in the requirements of colleges There are still 128 institutions for medical instruction in the

United States and Canada, the same aggregate as at the date of the last report But there were 760 less students in attendance upon, and 273 less graduates from, the sessions of 1884–85, than upon and from the sessions of 1883–84 In the United States there were 953 fewer students and 278 fewer graduates, in Canada there were 176 more students and 5 more graduates The schools are classified as follows regular schools, 101, homœopathic 13, eclectic, 11, physio medical, 1, and miscellaneous or mixed schools, 2 The number of medical students in 1882–83 was 13,088, in 1883–84, 12,762, in 1884–85, 12,002 In 1881–82 the number of medical graduates was 4555, in 2882–83, 4215, in 1883–84, 4101, and in 1884–85 only 3831 The increase in past years in students is most conspicuous in the smaller provincial schools, while in the large cities—Boston, New York, Philadelphia, Baltimore, Cincinnati, Chicago, New Orleans, and St Louis—there has generally been a decrease Thus the number of matriculants in medical schools in New York has fallen from 2209 in 1880–81 to 1829 in 1884–85 This fact may be interpreted in two ways It may either mean that the metropolitan schools are getting more rigid in their requirements, or that the provincial schools are getting to be better educational institutions We incline to the latter belief The decrease in the number of graduates, noted above, is most satisfactory, indicating as it does a recognition on the part of the rising generation of the fact that in the United States, of all professions the medical is and for years has been the most overcrowded —*The Lancet*, February 6, 1886

SPECTROSCOPY OF BLOOD —At the recent meeting of the Congress at Grenoble, says the *London Medical Record*, M Henocque explained his new method of examining the blood with the spectroscope The blood in the subungual region of the thumb is carefully examined, then the time necessary for the reduction of oxyhæmoglobin is ascertained, the blood is then placed in white porcelain capsules, when the presence of methæmoglobin can be recognized The method is clinically useful A stratum of blood is placed between thin glass slides superposed at an acute angle this arrangement is called by M Henocque a hæmatoscope It shows the necessary quantity of hæmoglobin with reference to the thickness of the strata M Henocque has recently invented a chromometric method, in which the hæmatoscope is placed on an enamelled plate, which shows directly the quantity of oxyhæmoglobin contained in the blood examined M Henocque showed thin models of hæmatospectroscopes, one very simply constructed for the use of students, and another adapted for carrying out minute and delicate researches Both instruments were constructed by M Lutz, optician, of Paris

ASSOCIATION OF PHYSICIANS AND PATHOLOGISTS —In view of the fact that each one of the natural divisions of medicine, except those of general medicine and pathology, is represented in this country by a special society, it has occurred to some members of the profession that a similar Association of Physicians and Pathologists is desirable Two preliminary meetings were held in New York City on October 10th and December 29th, respectively, at which the matter was thoroughly discussed, and, after a general expression of opinion, it was finally decided 1 To form an Association of Physicians and Pathologists, of which the number of members shall be limited to one hundred (100) 2 To hold an annual meeting in the month of June in the city of Washington 3 To hold the first meeting on Thursday and Friday, the 16th and 17th of June, 1886, with Dr Francis Delafield, of New York, as President

SAPPEY'S TREATISE ON THE LYMPHATICS —At the meeting of the Academy of Medicine, of Paris, on February 2, M Sappey presented a copy of his "Treatise on the Lymphatics," which was commenced in 1847 It consists of descriptive text and an atlas of forty-eight plates At the same meeting of the Academy he presented two quarto volumes, one of which was his "Recherches sur les Elements figurés du Sang dans la Serie Animale," the other a work relating to the respiratory apparatus of birds, and, finally, four volumes representing the last edition of his "Descriptive Anatomy"

ARCHIVES SLAVES DE BIOLOGIE —M Maurice Mendelssohn and M Charles Richet have founded a journal entitled *Archives Slaves de Biologie* It will appear every two months, and will contain original articles from scientific Sclavonic authors whose works are intelligible to their fellow countrymen only unless interpreted in another language MM Mendelssohn and Richet have had the happy idea of reproducing the valuable memoirs of eminent Sclavonic professors and scientists in a form accessible to all nations French is so generally spoken and understood throughout the civilised world, that the *Archives Slaves de Biologie* may be considered to be of universal utility

DR FILEHNE, teacher of Pharmacology in the University of Erlangen, has accepted the Chair of Pharmacology in the University of Breslau

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U S NAVY DURING THE WEEK ENDING FEBRUARY 20 1886

Clark, J H, Surgeon, detached from the "Hartford" on the reporting of his relief, Medical Inspector Bradley

Bradley, Michael, Medical Inspector, ordered by steamer of March 10 from New York to Aspinwall, thence to Panama and to the "Hartford" as the relief of Surgeon J H Clark

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U S MARINE HOSPITAL SERVICE FOR THE TWO WEEKS ENDED FEBRUARY 20 1886

Austin, H W, Surgeon, to proceed to Richford, Vermont, on special duty Feb 8, 1886

Urquhart F M, Passed Asst Surgeon, to proceed to Richmond, Virginia, for temporary duty Feb 16, 1886

MALIGNANT COLLOID VEGETATIONS OF THE UTERUS

A Clinical Lecture delivered in the Hospital of the University of Pennsylvania, on February 10, 1886

BY WILLIAM GOODELL, M D ,

PROFESSOR OF GYNÆCOLOGY IN THE UNIVERSITY OF PENNSYLVANIA AND GYNÆCOLOGIST TO THE HOSPITAL OF THE UNIVERSITY

The first case that I shall present to you to-day, gentlemen, is a case that has been sent to me because of difficulty in diagnosis The case has been examined by several physicians, and as there exists great obscurity and difficulty in arriving at a positive opinion, it possesses more than usual interest Such cases you will encounter, and they will puzzle you exceedingly unless you have seen such a case to guide you

The patient is over 40 years of age, she has had six children, and you see how very greatly distended her abdomen is Her menses have always been regular and during the last three months they have been very profuse Now I ask her whether she has bleeding after sexual intercourse, and she tells me that she has Why this should occur it is not hard to imagine, for it is due to the male organ impinging on diseased tissue, the blood-vessels of which, on account of the disease, are very brittle and friable, easily broken down Now at the first blush I would say that these symptoms look very much like carcinoma of the uterus Of course this hæmorrhage might be due to polypus hanging down from the os, but polypi are very unusual in women who have borne children, they are a disease of sterile women and old maids, these growths are the results of the constructive energy so great in the uterus, and which, not being utilized to construct offspring in those who are sterile and in old maids, results in the formation of such growth as polypi Well now, we have gone so far, let us look further into the case This woman complains of pain in her back and she tells us that she has a very offensive discharge from the vagina During the last three months her abdomen has swollen very much

These abdominal tumors will often bother you very greatly in diagnosis I could, of course, give you hard and fast lines, such as you read in the books, but even then you would very often go wrong Some years ago I was positive that I had to do with an ovarian cyst, and when I operated it proved to be ascites On another occasion when I was equally sure of a cyst, after working for half an hour I found that I had to do with a renal cyst This woman has been several times tapped on the supposition that she is suffering from ovarian cyst Now by vaginal examination I have detected carcinoma, which I believe has extended upwards until there is, so to speak, a saddle-bag carcinoma lying over across the spinal column, pressing on some of the large blood-vessels thereabouts and giving rise thus by interference with the circulation to the fluid in the abdomen Now what would point to ascites and what would point to ovarian cyst? In the first place we must make this examination under great disadvantages, owing to the distended condition of the abdomen But we note that the abdomen is less prominent, less distended in its most prominent part than it would be if the fluid were encysted When the fluid is free to move, it sags down more or less to the sides, while if encysted it would project more prominently in front, when free it bulges more on the sides If the fluid is ascitic we will have resonance in front, because the intestines, containing gas, will float on the surface of the liquid, but look out here, for if the accumulation be very great the intestines may not get all the way up hence we may have as we do have here, dulness at first, but on deep pressure we secure resonance Also there may be adhesions that will bind down the intestines, and in this way we will also have dulness If ascitic we will have dulness in the flanks, for here the fluid comes to the surface It may happen that in ovarian cyst the intestines will get in front of the cyst, and in such an event we will have resonance, so that you see how much confusion we may have in arriving at a conclusion

The crucial test will be in making an incision and drawing off some of the fluid Before making the incision I will deaden the sensibility of the part by applying to it a piece of ice, on which I have put some salt I choose the linea alba as the site of the incision, because it is free from blood-vessels, laterally we might wound the epigastric artery or some of its branches, and this accident is by no means a trifling one But you cannot always select this point, and the rule is to tap wherever indications demand without reference to the blood-vessels When this case was previously tapped, after a time the fluid seemed to be arrested and it ceased to flow through the canula, which caused the gentleman who had the case in charge to think that it was an ovarian cyst, well, now, there may be a cyst here, but if there is I am of the opinion that there is also ascitis I have seen cysts that were caused by, or at least consecutive upon, sarcoma, but they do not, as a rule, accompany carcinoma The fluid of ascitis is usually clear and of a straw color, but it may be slightly tinged with green, that from an ovarian cyst is generally darker, it is often chocolate colored, but here again I must caution you, for we may have blood in ascitic fluid, when it will be somewhat darker in color

Now I have introduced my trocar, but the fluid comes through the canula only in drops, what is the matter? I must have struck a solid portion of the growth, there is some bleeding, but the flow of liquid is greatly obstructed There must be here a growth of great magnitude, for you see I introduced the aspirating needle some distance above the pubes Now I move the canula about and I get a somewhat lighter fluid There certainly must be ascitic fluid around this growth, the needle was passed into the growth and now when I move it around I get the surrounding fluid This fluid is so thick, so glue like, that I am inclined to think that we have here a colloid If you cannot withdraw this fluid by the aspirator or by the trocar, what can you do? Why, if you consider it wise, make an incision and turn it out, but it would hardly be wise to resort to such a procedure in this case, when we know that the woman has carcinoma Now you see this fluid oozing out when I remove the canula, it will continue to ooze for some time When she coughs you notice the fluid flows more freely, this is because the coughing throws the liquid in front of the growth, and it thus more readily escapes It is always best when you start to remove a collection of fluid to remove it all before you stop, and not leave any to ooze out That should be the rule in all tappings, but especially in the case of ovarian cysts, for if the fluid is allowed to ooze out it may set up a severe inflammation, and very serious results may ensue Therefore I would condemn as a bad plan that, which you will often hear recommended, of inserting a hypodermic syringe into an obscure tumor and removing some of the fluid for examination Through this very minute opening sufficient fluid may escape to cause a fatal peritonitis Now that it is a good rule, it is not so important where the fluid is ascitic, but it is a good and safe rule to follow in all cases of fluid accumulations, for even in ascitic collections the oozing fluid may light up an erysipelatous inflammation at the point of emergence

Of course it is not always that you can completely evacuate a fluid collection, but when you can, always do so In the case of a thick colloid it is obviously impossible to do so I prefer always to avoid tapping for ovarian cysts, preferring greatly to perform the operation of ovariotomy Remember when you do tap, first to benumb the surface with ice and salt, second, to select the linea alba if possible, and third, if you happen to wound a blood vessel, to be prompt in your measures for relief I prefer to use the aspirator rather than the trocar, for this very reason, that I think there is then less danger of wounding the vessels If, an hour or two after the tapping, the woman is pale and weak, looks as though she were losing blood, you have grounds to fear that you have wounded a vessel in the abdomen or in the sac Then pick up a bunch of the abdomen about the point of incision, transfix it with a long needle and pass around this a figure of eight, on the supposition that the vessel that has been wounded is in the abdominal wall But suppose the symptoms of hæmorrhage continue after this procedure, what must you do? You must then conclude that you have wounded a deep vessel, from which internal hæmorrhage is taking place, and the only thing you can do is to proceed at once with the operation

You may ask me now why I do not cut down here and empty out this colloid mass I answer, because there is here the complication of extensive malignant disease, and I feel satisfied the woman's days are numbered This malignant disease, I believe, involves the broad ligament, ovaries, and fundus of the uterus I would not be at all justified in operating in such a case I cannot say positively why this fluid failed to come through the canula, but I am inclined to think that there are extensive adhesions between the tumor and the abdominal wall at all points but one, and that my needle failed to strike that one point

To go back to my remarks about tapping, there is one exception to the otherwise absolute rule not to tap in ovarian cysts, and that is to be found in cases of women who have heard that some neighbor has been greatly relieved by tapping, such women will not listen to the radical operation, will insist upon tapping, and in such cases you will have to yield to their importunities Still further, when the tumor is flaccid and there is very marked fluctuation, from which you infer that the wall of the cyst is very thin and it is not pulled down, you may tap under the assumption that it is a parovarian cyst, located in the broad ligament, on one side or the other These parovarian cysts are not uncommon, and tapping is a perfectly justifiable method of treating them, for in fifty-five per cent of the cases there is no return. I really believe that in the aggregate the tapping of ovarian cysts is a more fatal performance than is the operation of ovariotomy Take, for instance, one hundred cases of tapping and an equal number of ovariotomies, and I believe we will have a greater proportion of deaths in the former *This is due to* the fact that you cannot always tell beforehand what kind of a fluid you have to deal with, suppose you have a colloid cyst and you let some of this fluid out into the peritoneal cavity, you will be very likely to have a fatal peritonitis Here is some parovarian fluid that I removed in 1881 You see how clear and limpid it is, it is almost like water, but in *ovarian* cysts the fluid, as I have said, and as you see in this sample, is darker in color (chocolate colored) and more irritating to the peritoneum Again, the danger is not only from fatal inflammation, but if it does not go that far it is at least very likely to cause annoying adhesions Again, it is not uncommon to have one large cyst and grafted on to this numerous baby cysts. In the radical operation these babies are so small that they do not complicate the removal of the parent cyst, but it is a fact that when you tap and remove the fluid from the mother cysts, these babies take on rapid growth, and when you finally come to operate a much larger incision will be required to remove the disease than would have sufficed in the first instance.

To go back again, I would say that wherever we have a wound of the surface from which blood or bloody fluid trickles, we are then very likely to have erysipelas. In my younger and less experienced days I was wont to resort, in cases of dropsy from heart or kidney disease, to a method that you will see every now and then recommended, of puncturing, with a bistoury, the dropsical limb. It was supposed to let the fluid drain away and thus afford the patient relief. So it will, but in very many cases it will cause erysipelas of the part, hence I have given up this practice. Another serious objection to all kinds of tapping is that the fluid re-accumulates very rapidly. I have seen it re-accumulate in an ovarian cyst, after tapping, at the rate of more than a pound a day, which you must remember represents an immense waste of strength, for this fluid is very rich in nutritive material. So, in conclusion, I would again say that, in dropsies, it is best not to tap.

VEGETATIONS OF THE UTERUS

Here is a woman who was sent to my office a few days ago for an opinion and treatment. She is 36 years old, has had six children and one miscarriage, that occurred thirteen months ago, when she was four months advanced in pregnancy. Her menses have been regular, but for the past three months the flow has been very profuse. She now loses blood when she moves about, and is very much reduced in strength in consequence, but I do not think the hæmorrhage alone has been sufficient to account for the loss of strength. Upon examination, I find a slight laceration of the cervix, the uterus is a little prolapsed, and when I pass the sound it measures only three inches. I can find no tumor either with my finger in the vagina or by external examination over the abdomen. Why then does she bleed so? My inference is that since there is no tumor the hæmorrhage must be due to vascular vegetations in the cavity of the uterus, yet the organ is not large enough to give me the idea that they are very abundant, for if they were the sound ought to give me a measurement of at least three and a half inches, whereas it gives only three. However, I am going to scrape or curette the uterus and we will see what we get.

You notice that blood oozes from the vulva, the passage of the sound has caused hæmorrhage. Why do I think there are vegetations here? Because I find this laceration of the cervix, for such a laceration is very likely to cause vegetations, since it is a source of irritation, and thus invites blood to the part. Now I prefer to use a sharp curette. I can accomplish more with it, but I advise you to use the dull instrument until you have become proficient in handling it. You see I use only two, or at most three, fingers in handling it, if I were to grasp it roughly with my whole hand, as you would be apt to do until you have acquired dexterity, I would likely do the womb some injury. Yes, I am right, here you see these vegetations that I have scraped away. When the woman first came to me complaining of hæmorrhage I was inclined to think that it was probably due to the retention of some of the products of conception, left behind at the time of her miscarriage, for I misunderstood her broken English (she is a German), and supposed that the miscarriage had occurred only three months ago, but when I found that thirteen months had elapsed I abandoned this idea, for if a decomposing mass had been retained for that length of time the evidences of septic infection would have been more marked. I find most of these vegetations in the cornua. I feel the grating, and now I have removed a great many very small ones. This scraping will often put an end to what has been a persistent and annoying hæmorrhage for years, but let me urge upon you not to promise too much. This is a failing of young men, early in their career, they take a roseate view of everything and promise so much that they are frequently doomed to disappointment. Say you are hopeful, or are quite confident that you will be able to afford relief, but do not absolutely promise, leave promises to quacks, for this is their stock in trade.

At the present time I am being very much bothered by a correspondence with a lady who contemplates having her cervical canal dilated. I performed this operation on a neighbor of her's, who suffered terribly from dysmenorrhœa, and as this lady is similarly afflicted she thought to have the same operation performed. She desires the operation, but is very nervous about it. After writing and asking me all manner of conceivable questions, I finally received from her, yesterday, a letter in which she bluntly asked me whether there was the slightest danger in the operation. Now what was I to say? All I could tell her was that I have performed the operation some two hundred odd times, and that I have never yet had any serious results. I could not promise absolutely that there was no danger at all. You cannot make such a broad promise about any operation, even of the most trivial nature, if you do, you will often get caught in very unpleasant positions. Suppose you are attending a case of typhoid fever and you make a positive promise that the patient will get well, and he dies, there will be in the family a revulsion of feeling that will make it very disagreeable for you. You will be sometimes asked, as I have been, whether the simple passage of the uterine sound can be attended with any danger. I used to answer this question in the negative, but since the occurrence of a fatal peritonitis, in a case where I simply passed a sound, without lifting the uterus at all, I have become much more conservative in making promises. A celebrated New York gynecologist once introduced a pessary, as the result of which a furious inflammation was developed and the patient nearly lost her life. On one occasion I scraped away some vegetations from the uterus of a bride, who was suffering severely from menorrhagia, the parts were so small that I was obliged to dilate with sponge-tents before I could introduce the curette. In two days she was dead. The fatal result in this case I attributed more particularly to the sponge tents, and I have abandoned their use, resorting to the dilator when I find the parts too small to admit the curette. I would say, but I would not promise, that there is very little risk in curetting, if the patient keeps her bed for awhile and is careful. Now after scraping, I swab out the uterus with tincture of iodine, which is antiseptic and also completes the destruction of those vegetations which my instrument has bruised but not removed.

These cases of unexpected death are most distressing. Suppose I remove a cancer of the womb and the woman dies, the result is not shocking, for it is a result to be feared, and besides it is only a question of time when the disease would have killed her. But if death ensues from such an operation as curetting or dilatation of the cervix, both resorted to not for the relief of conditions that endanger life but merely to make the woman more comfortable, it is truly shocking. But in all my curette operations, I have never had serious results save only in the case referred to, and where, as I said, I laid the blame on the sponge tents.

We will keep this woman in the hospital until all soreness has gone. We will take her temperature three times a day, and the moment there is any rise we will give her an opium suppository. I cannot tell you how much faith I have in the power of opium, given early, to check the occurrence of inflammation about the female pelvis. In puerperal women, after doing well for two, three or four days after labor, they may wake up some morning with severe pain in the abdomen and the temperature up to 103° or 104°. This means a commencing inflammation of the broad ligament, and it can be nearly always checked in its incipiency by a suppository of opium, so that if a puerperal woman has an intelligent nurse, I am in the habit of leaving some opium suppositories, to be used if these conditions develop. If you can give a hypodermic it will check it even more rapidly. Here also does quinine come in well, and I would give from five to ten grains at a dose, repeating it until the head is affected. The ice cap to the head and the ice cap to the abdomen must not be neglected. I always use it to the head if the temperature gets up to 101°, and if above this point, to the abdomen as well. If there is moderate soreness I apply a poultice. There is one other remedy in which I have great faith, namely, digitalis. After putting ice on the head and stomach, I give ten drops of the tincture of digitalis every hour, and increase it to fifteen or twenty drops if it does not bring down the pulse and temperature. It may irritate the stomach, but I have never seen other toxic symptoms, as the effect on the head will warn us in time when to stop its use.

THE MECHANICAL TREATMENT OF THE VOMITING OF PREGNANCY[1]

BY JOSEPH TABER JOHNSON, M.D.,

OF WASHINGTON, D.C.

The vomiting of pregnancy is a condition which the physician is frequently called upon to relieve, and in the great majority of cases he is either successful in his treatment, or the patients get well by themselves. There is, however, a small proportion of cases which are not curable by any treatment short of the complete removal of the cause, and a still smaller number which resist all treatment, abortion included, and finally starve and die.

In that class of cases usually referred to as the "uncontrollable vomiting of pregnancy," the books tell us that nearly every remedy named in the materia medica has been employed in the vain attempt to cure. *Some* of these sufferers are *relieved* by treatment; *some* for a time seemed to be cured, while the trouble recurs later on; *others* are not benefited by any drug, and are sick from almost the first to the last days of gestation, but not severely so, and, as above stated, some die, either from the direct results of the continued vomiting, or from some intercurrent affection set up or aggravated by it. While in all cases the vomiting is caused by the pregnancy, this cause does not operate in the same manner in all persons, inasmuch as remedies which seem to cure some have no effect upon others, or upon the person cured in a subsequent pregnancy. For instance, *drugs* which relieve certain nervous and emotional women do not relieve patients who are not nervous or emotional, or when the special cause resides in an anteflexed or retroverted uterus, a granular os, or a rigid cervix. So that any suggestion which gives promise of aid in this distressing class of cases would naturally attract attention, and should be given an opportunity, at least, to prove its right and title to a place upon the list.

Before referring to special modes of treatment, I wish to briefly draw attention to a few statements bearing upon the mortality of this affection, partly by way of apology for occupying the time of this Society with a subject which is usually, and perhaps too often considered one of the trivial or slight ailments of pregnancy. That in certain rare cases of this disturbance, which have been called sympathetic by some, emotional by others, and reflex by all writers the vomiting has become so dangerous to life as to demand relief at any cost, we have abundant evidence in recent journal literature and text books upon midwifery. It is rare that fatal results follow these annoying symptoms. It is perhaps not within the experience of a single member of this Society that death has been the direct result of the uncontrollable vomiting of pregnancy, as it is called, and yet we have altogether too numerous examples of the mortality accompanying this condition. Thus, Barnes[2] says that in a far larger proportion than is commonly accepted death is the termination, unless averted by abortion "It is impossible," he says, "to state the cases numerically, but every author of experience gives examples of fatal cases The danger of the affection is sometimes doubted, and this doubt, founded on subjective ignorance, is urged as a plea against the induction of labor" McClintock, with a very moderate amount of research, says "I have been able to collect close on fifty authentically recorded cases, and I know of others which have not been published We ourselves have seen nine fatal cases"

---

[2] Barnes's System of Obstetric Medicine and Surgery, p. 274.

Lusk, in the last edition of his now famous work on Midwifery, says (p 126) "In general, with severe cases, the prognosis is bad," and quotes from Joulin, who has recently reported 121 cases, with forty-nine deaths Without treatment, of fifty-seven cases twenty eight were fatal, with treatment, where abortion was induced, of thirty six patients nine only died By the method of artificial interruption of pregnancy, McClintock reports in thirty six cases the saving of twenty-seven lives

Grailey Hewitt, in a recent paper upon this subject, states that "numerous cases have been recorded during the last fifty years in which death has resulted from, or in connection with, the excessive and severe vomiting of pregnancy" He says that "the largest number of fatal cases observed by any one individual is twenty, and that since the practice of inducing abortion has somewhat increased in dangerous vomiting, the number of fatal cases has decreased"

As the advocates of the mechanical mode of treatment almost deny the agency of the stomach in the vomiting of pregnancy, and claim that the administration of medicines *per ovum* or *per rectum* is of no avail, and are consequently worse than useless —as they consume valuable time—I thought that it might be profitable to consider in a group by themselves the principal mechanical methods in the practice of which drugs are excluded as unnecessary I do not intend, therefore, to open up the entire question of the causation and treatment of this subject, which has recently been discussed in our Obstetrical Society, but to confine this discussion to the consideration of what I call its mechanical treatment

As I recently had an opportunity of testing the merits of Copeman's method by dilating the *cervix uteri* for the relief of an aggravated case of gravid nausea and vomiting, I have written out the main points of the case, which are as follows

Case—Late in the evening of January 7 I was called by telephone to see Mrs X, on account of uncontrollable vomiting which had resisted all treatment for more than a month Her husband gave me the following history of the case, as near as I can recollect it His wife had missed her period just two months For the first three weeks she had not suffered unusually, but after that time her sickness increased, and from troubling her in the morning, it gradually became worse until, at the end of her first month, she was vomiting throughout the entire day, and it soon became so constant that she found no relief at night Indeed, after another week it was worse at night than during the day For a month a physician had been in attendance, and part of the time two They did everything they could with medicine to control the vomiting, but without success From thirty to forty different remedies were tried, but the vomiting continually grew worse Finally, Mr X informed me, the doctors thought everything had been accomplished which lay within the power of drugs, and fearing the lady would die if not soon relieved, they suggested that an abortion be induced in order to save her life This suggestion was agreed to, and several ounces of ergot were administered, only to be vomited as soon as swallowed, and without producing any other effect So the patient was one day placed in position with her buttocks at the edge of the bed, and "some fluid was injected with a small syringe into the uterus" This produced little or no result The husband got the impression, from some consultations he partly overheard between the physicians, that doubt was entertained whether his wife was pregnant at all He felt certain that she was, and was exceedingly anxious about the result He informed me that he called at his physician's house, and after waiting some time, not finding him at home, wrote him a long letter expressing his views of the case, and announced his intention of changing physicians and courteously requested his bill

After this statement I took charge of the case and examined his wife I found the pregnant uterus somewhat prolapsed and anteverted I corrected this displacement by digital manipulation, but as no relief followed, I directed the patient to take absolutely nothing into her mouth, and that she be fed entirely by the rectum I also directed that she have, in addition to her milk and beef-tea, large doses of the bromide of potassium with a little brandy and about 10 drops of laudanum, to prevent rectal irritation, every four hours—a mode of practice inaugurated and often successfully carried out by a distinguished member of this Society, Dr S C Busey

When I called on the morning of the 8th I found that my directions had been strictly obeyed, but the patient was no better Indeed, she had vomited all night, and some of the time had been quite delirious She had a dry, brown tongue, and a cadaveric odor to her breath She had been in bed four weeks, and both wife and husband asserted positively that for a month no food had been retained, and for the week previous to my seeing her she had taken nothing but ginger ale Her condition and appearance confirmed this statement Her face was somewhat swollen, but her body and limbs were greatly emaciated She had been unable to get out of bed for two weeks, and had the greatest difficulty in raising herself on her elbow to vomit, and some of the time the vomited matter was caught on towels as it was ejected from the side of the mouth I persisted for twenty four hours more in the use of remedies, mostly by the rectum, but had small powders of calomel, oxalate of cerium, ingluvin, bismuth, and finally morphine, in turn placed on her tongue The vomiting went on just the same I told the husband there was one other remedy which I wished to make use of, introduced and successfully practised by Copeman, of Norwich, England, and if that was not successful I would ask for counsel, and if agreed to, would put an end to the pregnancy, as I believed his wife would soon die if not relieved.

Perhaps at this point I should state that less than three years ago she had gone through with a somewhat similar experience, and had been under the care of a number of our best physicians. As the vomiting was not controlled, several changes had been made, and I am informed that all the physicians in attendance had considered her dangerously ill—although the vomiting continued until the birth of the child, which was thought to have occurred prematurely. She was kept alive for three or four months on rectal alimentation, and I am informed that her physician told the husband that his wife had made a very narrow escape, and that if ever she became pregnant again she would be very likely to die. How much of this statement is correct, I am unable to say, but the wife and the husband told me at different times and separately that her recovery was very slow, and that when she was finally able to ride out she was taken over to the Smithsonian Institution and was weighed with all her heavy wraps on, and then only weighed seventy six pounds, though her usual weight was 140. It was the belief of both Mr. and Mrs. X. that the patient had lost at least fifty pounds in the past month. I could readily believe this, as she was very thin, and the skin hung in loose wrinkled folds about her legs and arms.

In the *British Medical Journal*, for May 15, 1878, Dr. Edward Copeman published an article entitled "Dilatation of the Os Uteri for Vomiting in Pregnancy," in which he claimed that most, if not all such cases could be cured by the dilatation of the muscular fibres of the neck of the uterus—including those of the internal os in cases in which a less dilatation failed. In this paper he relates a number of successful cases. Several papers soon followed confirmatory of Dr. Copeman's practice, in British and American journals, notably one from Marion Sims, in 1880, and published in the *Archives of Medicine* for that year, and one by W. Gill Wylie, in the *Medical Record*, of Dec. 6, 1884. The recent works of Lusk and Barnes recommend this practice as a proper and justifiable mode of treating these cases. I therefore felt that I was warranted in giving it a trial, and after fully explaining to the husband and wife what I proposed to do, with their consent, on the morning of January 10 I dilated the cervix uteri with my finger. I found it impossible at first to insert my finger, and therefore, fixing the cervix with a fine tenaculum, I expanded the fibres of the external os with the blades of Bozeman's uterine dressing forceps. I then proceeded with my finger, and with a pushing and boring motion stretched the cervical canal until it admitted my index finger to the internal os, but not through it. I found tight, unyielding circular bands at the external os, and also near the internal os, which finally gave way. There were but a few drops of blood, and those came from the puncture of the tenaculum.

I continued the rectal injection of food, and when I called in the evening I found that the patient had vomited but once, and that she was feeling very comfortable, and much encouraged. The vomiting was occasioned by the drinking of a tumbler full of milk just before my arrival. The stomach had been perfectly quiet since the dilatation; the patient began to feel hungry, and, thinking herself cured, indulged in this full glass of milk, with the result stated. She vomited none that night, and the next morning could take food without the least nausea, but she soon began to have pains, and by night regular uterine contractions set in, and by midnight of the 12th instant she miscarried a two months fœtus. The next day she ate freely of lamb chops and milk toast, and has not vomited since, and was soon up and walking about the house.

The theory of Copeman, that this form of vomiting is produced by the failure of the rigid fibres about the internal os, and in the cervix uteri, to soften and dilate under the influence of advancing pregnancy, finds some confirmation in the occurrence of nausea and vomiting which so frequently occur to women in labor. As uterine contractions occur and continue, producing the physiological softening and dilatation necessary for the passage of the child through them, repeated vomitings take place. This has been considered so usual and necessary an accompaniment of the average normal first stage of labor, that in cases where the dilatation was very slow or would not begin, nauseating remedies have been frequently prescribed with the hope of facilitating this process. In that form of dysmenorrhœa, also, where there is a hard, unyielding, narrow cervix, nausea and the most violent and distressing vomiting may precede and accompany the menstrual periods. I have recently cured some of these cases by Goodell's method of rapid dilatation of the cervical canal, and the vomiting disappeared also.

In referring to the usefulness of Copeman's method, Dr. Gill Wylie says: "If there is a doubt about the amount of dilatation, the best test is to put the patient on her back, and when the index finger up to the first joint can be easily passed into the cervix, the dilatation is sufficient. Before resorting to abortion in any case where dilatation up to the os internum failed, I would first dilate the os internum and wait long enough to see if it would stop the vomiting, for this can be done in some cases without abortion necessarily following.

"*Conclusions*.—1. That nausea and vomiting, or morning sickness in pregnancy, should not be considered and treated as merely one of the symptoms of pregnancy, but, as a rule, as indicating an abnormal condition of the tissues of the cervix uteri, due to imperfect development, disease, or the effect of disease on the tissues of the cervix.

"2. That any pathological state which interferes with the softening and other changes which the cervix undergoes during pregnancy, may cause nauseal vomiting.

"3. That in most cases relief is obtained by freely dilating the cervix uteri below the os internum, and in many instances it is the only means by which relief can be had. It is true that inducing abortion will give relief, but to accomplish this the cervix uteri must be dilated.

"4 That in many cases specific medicines given by the mouth are useless, and, as a rule, should not be used until a local examination is made and the indications for local treatment ascertained "

In Vol XXVI of the Trans of the Obstetrical Society of London, page 273, is a very elaborate article by Prof Grailey Hewitt, in which he sets forth at great length his views as to the causation of the vomiting of pregnancy He claims that all, or nearly all cases are produced by the ante displacements of the gravid uterus, and cites the histories of many patients who were successfully treated by a restoration of the uterus to its normal position, requiring none of the medicines usually prescribed subsequently Hewitt combats the theory of Horwitz, of St Petersburg, who, in a recent paper, gave the histories of ten cases of the severe or uncontrollable vomiting which he accounted for on the ground of a degeneration of the uterine tissues resulting from a mild form of congestion and inflammation Hewitt contends that the histories given by Horwitz plainly show that in his cases there was a displacement of the uterus, which could have been restored by appropriate mechanical treatment, and thus cured of a very dangerous malady Notwithstanding the best attention was given by Horwitz, three of his cases died and several aborted

Though Grailey Hewitt would approve the induction of abortion in order to save the life of his patient, and has several times practised it, yet he thinks that this very disagreeable procedure would not be forced upon us if more attention was given to the position of the gravid uterus, and its displacements corrected by appropriate mechanical support He has devised an instrument which has an exceedingly appropriate name, inasmuch as he calls it his "cradle pessary," in which the fœtus is probably rocked to sleep while listening to the swish swash of the bag of waters, and the gentle murmurs of the umbilical cord *and placental souffle*

The discussion of Hewitt's paper was participated in by some of the best talent in the London Obstetrical Society—calling to their feet such men as Playfair, Braxton Hicks, Barnes, Galabin, and others, who, while they accused Hewitt of riding a favorite hobby rather hard, generally agreed that many cases of gravid nausea and vomiting could be cured by a replacement of the gravid uterus—while it was the general view, also, that this mode of treatment was not so universally demanded as the distinguished author of the paper imagined Cases were cited by Hicks and others in which replacement of the uterus did not control the *vomiting, and still* other cases where severe vomiting occurred entirely independent of any gravid displacement It was conceded, however, to be a very valuable mode of treatment in appropriate cases Incidentally the Copeman method was generally endorsed Several cases were cited, however, which terminated as mine did where it was practised Grailey Hewitt refers to the history of one case quite similar to the one which forms the basis of this paper, in which he replaced the anteflexed gravid uterus and dilated the hard rigid cervix at the same time There was an immediate arrest of the vomiting which was seriously threatening the patient's life, but two days subsequently she aborted

I may refer here to a case I saw several years ago, where a lady was suddenly attacked with the most intractable, constant and uncontrollable vomiting I ever saw She was not relieved by anything I did during the greater part of three days and nights Finally I obtained the key to the situation when informed that she was possibly ten weeks pregnant with her first child, and that the vomiting promptly set in after she had climbed with a party of friends to the dome of the Capitol I immediately asked for an examination, which was at first refused, but when informed that relief to her constant and increasing suffering might be obtained through information thus gained, objections were withdrawn I found the gravid uterus much displaced and anteverted, and at once replaced it with my finger The relief was instantaneous She did not vomit again, and could eat without trouble from that time on

Dr H F Campbell, of Georgia, who was elected President of the American Medical Association at the meeting recently held in this city, in a paper covering 120 pages, presented to the American Gynecological Society at its last meeting, also held in this city, agrees with Grailey Hewitt that the vomiting of pregnancy is produced by gravid displacements, but differs from him as to the mode of treatment Dr. Campbell asserts that the genu pectoral posture is the safest and most successful method of mechanical or any other treatment Ten years ago the celebrated author of this elaborate paper called attention to this subject, and in addition to the treatment of "gravid nausea," as he calls it, proposed to treat all cases of uterine displacement except inversion by placing the woman in a position where the laws of gravity would be reversed By drawing back the perineum the air rushes into and balloons the vagina, and as the intestines sag downwards and forwards, the uterus gravitates or swings into place, thus overcoming its displacement In cases in which serious jamming or impaction occurs, and slight adhesion takes place, he assists the uterine replacement by the fingers or by pneumatic or hydrostatic pressure A Barnes's dilator or Braun's colporynteur is placed in the rectum or upper part of the vagina, and inflated with air or water, the impacted organ pried out of its bed, and thus assisted to swing down into position

In most cases it is only necessary to place the patient in the true genu-pectoral posture to accomplish the result desired When re-position is thus effected nausea ceases, medication is avoided, and the patient is fed by rectal alimentation until the stomach sufficiently recovers its tone to receive and digest food It may be necessary to practice replacement several times before a complete cure is effected Campbell relates a number of cases cured in this way without drugs, and states that many medical friends in his part of the State are succeeding in curing gravid nausea by his method While the impacted pregnant uterus is often lifted out of the pelvic cavity and above the s p by the aid of some of the same forces which are employed by Campbell, their mode of employment differs, and the object differs In one case it is done simply to overcome the impaction which, if left uncured, would result in a fatal interference with vital functions; in the other, before such interference would occur from the size of the uterus, to cure the nausea resulting from such displacement. Campbell closes his paper in the following words: "Believing, as I do, that gravid displacement is indeed the true source of all the observed histological alterations in the gravid uterus, and also that this gravid displacement is, as I have said, the *fons et origo* of the gravid nausea, I must urge as my first and last expedient for the relief of all these common evils arising from a common cause, repeated postural pneumatic reduction in the genu pectoral position."

In the *London Lancet*, for February, 1878, Dr. M. O. Jones, of Chicago, published a paper on "Vomiting in Pregnancy," and advocated in certain cases the local application of nitrate of silver to the os uteri as a cure. This mode of treatment could not have originated with Dr. Jones, as Dr. Marion Sims reported a case a number of years prior to Jones's paper, in which he cured a noble lady in Paris who had been given over to die by a number of eminent physicians who had religious scruples against the induction of abortion. Sims reports that from the first application the relief was marked, and that in a few days she was completely cured. The recovery was heralded as little less than a miracle. I have had one such case, and was greatly surprised by my perfect success in curing a patient who had been confined to bed for two weeks, vomiting everything she would eat, until finally the smell of food caused emesis. She was very weak, and considerably emaciated. She had taken many different remedies with no benefit. Injections of the bromide of potassium did no good. She was kept alive, I believe, by the injection of food *per rectum*. The efforts to vomit continued, and were not relieved until the nitrate of silver was applied. She immediately became better and the vomiting soon stopped, and she finally gave birth to a fine healthy child. I saw this case in consultation with Dr. S. L. Cook, no Capitol Hill.

The last mode of mechanical treatment to which I shall refer is the artificial induction of abortion, and I refer to it in the same spirit in which I should refer to the last resource of our art in that very distressing class of cases which demands from the physician the performance of craniotomy in order to save the life of the mother. In both cases I should feel much regret that the obstetric art had failed in its high and holy mission, and was shorn of its crowning glory in falling short of delivering a live child from a live mother. In both cases I should accept this sacrificial practice only as a last resort, after all substitutes and alternatives had failed or were inapplicable—and in both cases I should in all conscience side with Barnes when he says that "a law of humanity, hallowed by every creed and obeyed by every school, tells us, where the hard alternative is set before us, that our first and paramount duty is to preserve the mother, even if it involve the sacrifice of the child." In this "last extremity of our art and the forlorn hope of the patient," as Professor Davis calls it, my experience is limited to the case related here this evening, and in this instance the abortion was unintentional and therefore accidental.

In those rare cases in which every other means had failed, including the mechanical methods which I have mentioned in this paper, and I was impressed with the conviction that the woman would die if not relieved, I should call a consultation, and unhesitatingly recommend, and if agreed to perform, artificial abortion. The exact mechanical methods I am fortunately not familiar with inasmuch as I have never yet seen a case where I thought it necessary to resort to this mode of treatment. The case narrated, of Mrs. X., came the nearest to it, and as the Copeman method in my hands and the hands of others has in several instances produced this result, I should recommend the dilatation of the cervix with an instrument or the finger up to the internal os, and if the vomiting was not arrested, and other means had failed, I should suggest that the internal os be dilated, and if pains did not soon come on, to pass a flexible bougie up to the fundus uteri between the membranes and the walls of the uterus. All means likely to lacerate the tissues—and among these I should include sponge tents—would be likely to do harm by producing absorbing surfaces and thus favoring the occurrence of septicæmia.

While I am not an especial advocate of any one of these modes of treatment as a new discovery destined to take the place of all other methods, I think that a due regard to the progress of the age and events demands of us that we consider and try the value of these comparatively new suggestions before resorting to such revolting and destructive practice as we have demonstrated in the beginning of this paper, may sometimes be required of us in order to save valuable lives entrusted to our care. When this form of mechanical treatment is agreed by competent consultants to be demanded by the sad exigencies of any case, I recommend that it should not be delayed until it is too late to save even the mother's life, as a number of cases have been recently reported where, notwithstanding the tardy removal of the cause, the patients finally succumbed. Relief came too late.

PERINEAL MEDIAN URETHROTOMY, REMOVAL OF LARGE QUANTITY OF SANDY GRAVEL, DILATATION OF URETERS, DOUBLE PYONEPHROSIS, HYPERTROPHY OF BLADDER, DEATH.

BY EDWARD HORNIBROOK, M.D.,

OF CHEROKEE, IOWA.

N. B. Batterson, æt. 51, consulted me July 17th, 1881, and gave the following history. Ancestors for several generations long lived and healthy. He enjoyed good health till ten years ago. Then had retention of urine brought on by heavy lifting. The physician in attendance retained gum elastic catheter for eight days. At the end of that time the patient passed large quantities of blood. He says that this was after, not before, removal of catheter. He has had constant vesical irritation since. Pus and mucus passed daily for first four years. He was then free from purulent or bloody urine for eighteen months For last two and a half years he has been passing bloody urine and pus at frequent intervals Hæmaturia has always occurred after lifting heavy weights, which he was often required to do in his employment as a grocer's clerk Requires to urinate every half hour, night and day Symptoms not relieved by recumbent position Has had frequent symptoms of a calculus passing through urethra, but never saw any After these symptoms he often passes large lumps of hardened mucus Has not passed catheter for last two years Bowels constipated and passages painful Prostate gland enlarged and tender Catheter passes easily, but there are two slight strictures in membranous portion of urethra Urine drawn by catheter alkaline in reaction and mixed with pus No stone in bladder

Under treatment, principally with the dilute mineral acids, benzoic acid and rectal suppositories, his condition was ameliorated until May 12th, 1885 He then complained of the usual symptoms of vesical calculus I readily detected stone, and advised operation Very offensive pus escaped during the examination After repeated trials I failed to grasp the stone with the lithotrite It was of large size and placed just above and behind the neck of the bladder, apparently lodged in a pouch from which it could not be removed He suffered little during the attempt, there was no shock, and he seemed as well as usual next day I recommended lithotomy, but the patient refused to consent to the operation

He passed from observation until October 12th, when he sent for me and urged me to undertake the operation, as his health was giving way under his constant suffering I reluctantly consented, as the urine was then strongly alkaline, contained large quantities of pus, and was horribly offensive

On October 20th, in the presence and with the assistance of several of my professional confreres, I performed the operation according to Allerton's method After dilating the prostate I introduced the scoop to dislodge the stone from the pouch in which I thought it to be imbedded, when it crumbled into small crystals On passing my finger into the bladder the whole mucous membrane seemed covered with an incrustation of this sandy gravel, which I was unable to remove without removing the mucous membrane with it I removed what I could with the scoop and irrigated the mucous membrane thoroughly with a strong stream of carbolized water By this means more than two ounces of this sandy gravel were removed Shreds of mucous membrane were also washed away

I retained a tube in the wound with the intention of practicing daily irrigation The next day the bladder was washed out till the water came away clear After a few minutes nearly an ounce of fœtid pus followed This convinced me that the pus was discharging from the kidneys, and added to the gravity of the prognosis

The washing out of the bladder was continued till November 9th, when he sank exhausted He suffered less after the operation than before

A post mortem examination was made twelve hours after death by Drs Sherman, Vail, and Burlingame, who kindly removed the bladder, kidneys and ureters for my inspection, as I was away from home at the time The walls of the bladder were an inch in thickness, the ureters both dilated so that they were at least three quarters of an inch in diameter, and there was about three ounces of pus in each kidney and its ureter

Many questions, of course, suggest themselves as to the etiology, the course of the disease, and the cause of the pathological conditions I will not attempt to theorize, but merely state the facts, leaving each reader to make his own deductions

Cherokee, Iowa, February 3d, 1886

MEDICAL PROGRESS

Increase in Number of White Corpuscles in the Blood in Inflammation, Especially in those Cases Accompanied by Suppuration —At the meeting of the Royal Medical and Chirurgical Society, on January 12, Mr T P Gostling read a paper on this subject Observations of Virchow, Nasse, and Malassez on the increase in number of white corpuscles in the blood in different inflammatory conditions were alluded to The estimations recorded in this paper by the author had been made with a Gowers's hæmacytometer, and the results were given in percentage numbers of red, and in relative numbers of white corpuscles, the normal number being taken as 1 white to 333 red corpuscles, as stated by Dr Gowers Estimations had been made in the following cases Case 1, iliac abscess, Case 2, pelvic cellulitis and probably abscess, Case 3, suppurating white leg, Case 4, suppurating tonsillitis, Cases 5 and 6, white swelling treated by the actual cautery, Cases 7, 8, 9, and 10, empyema, Cases 11, 12, and 13, phthisis, Cases 14 and 15, serous pleurisy, Case 16, lobar pneumonia, Cases 17 and 18, typhoid fever, Case 19, acute rheumatism In the iliac abscess, Case 1, ten observations were made on separate days before the abscess was opened The first half of these estimations showed the relative average number of white to red corpuscles to be 1 to 160, the second half 1 to 101 The abscess was then opened, and the proportion immediately fell to 1 to 383, after which there was a slight increase and then a steady decrease to the normal proportion, as was shown by the following averages 1 to 203, 1 to 223, 1 to 252 and 1 to 358 In Case 2, which was one of pelvic cellulitis and probably abscess, there was found, for a long period, a large increase in the number of white blood-corpuscles As was shown by the averages given below, these covered a period of 84 days, and each average was made from five estimations 1 to 148, 1 to 172, 1 to 150, 1 to 158, 1 to 167 During the above period, grave symptoms existed, but on May 15th, these began to improve, and at once the relative number of white corpuscles decreased to 1 to 250, and on May 19th reached the proportion of 1 to 366 It was thought that an abscess in this case had discharged by the bowel, and if so, the sudden fall would correspond with that seen in Case 1 Analogous conditions were found in the other cases The new series of observations were from cases of phthisis (Nos 11 and 12), in both of which cavities secreting pus existed in the lung Cases of serous pleurisy, acute rheumatism, typhoid fever, pneumonia, and cauterisation, were also considered with reference to the proportion of white corpuscles The following conclusions were drawn 1 White corpuscles are increased in number in suppurative inflammations, especially when accompanied by tension 2 They are slightly increased in parenchymatous inflammations 3 They are not increased in inflammations accompanied by serous or sero fibrinous exudation

Dr Sidney Ringer remarked that Mr Gostling seemed to him to have demonstrated the increase of white corpuscles in the blood in inflammation, and of the origin of this excess there were two chief hypotheses—that they were formed in the blood itself, or that they were absorbed from the suppurating parts He agreed with Mr Gostling in inclining to the second If that were so, it led almost of necessity to the conclusion that the corpuscles multiplied after escaping from the blood-vessels Dr George Thin said that there could be no doubt that the white corpuscles, after leaving the vessels, did multiply In his own examinations of the corneæ of rabbits, published about ten years ago, he had fixed them with osmic acid, and had observed them in all the stages of subdivision and multiplication The question whether the white corpuscles were ever formed from the tissues was one of deep interest and keen controversy He did not wish to pretend to decide it, but he thought that certainly no decisive evidence had been brought forward to show that pus originated from the tissues Mr Victor Horsley thought that Mr Gostling had certainly demonstrated the important point that increase of white corpuscles was connected with tension If the question of their origin at a particular inflamed part were at issue, the first thing to do would be to compare the blood of the artery supplying the part with the blood of the vein coming from it There was no support offered by the facts of Mr Gostling's paper to the theory that pus originated from fixed tissues, and that was in accordance with Mr Dowdeswell's conclusions Dr Angel Money had made some observations on the blood in phthisis and empyema and quite agreed with the results of Mr Gostling's most laborious researches He was rather surprised that Mr Horsley should seem to overlook the possible reabsorption of white corpuscles by the lymphatics Dr S Coupland felt much indebted to Mr Gostling for his facts, but remarked that he had not made the source of the increase of white corpuscles quite clear, and that had been felt by Cohnheim to be the most difficult point Dr Douglas Powell inquired how early in the case of iliac abscess Mr Gostling had begun his observations He said that it was fifteen days before the abscess had been opened, but was it before any collection of pus could be proved to exist? That was an important point, because tension was an important factor in the reabsorption of pus Clinical experience did not find such reabsorption common Mr Howard Marsh considered that, in surgical cases, abscesses were very commonly absorbed, and sometimes very quickly M Bryant agreed on this point of surgical experience, he had certainly seen pints of pus absorbed Dr Ringer suggested that in these cases the pus cells of the abscess had degenerated and changed their character before absorption Mr Gostling, in reply to Dr O'Connor, had only to refer to the very numerous tables of his observations which were hung on the walls, and showed the number of red corpuscles as very nearly normal—if, indeed, any exact normal standard could be attained, He had found a very marked increase in the white corpuscles before any distinct evidence of abscess formation could be obtained, both in the case of iliac abscess he had observed, and also in the two cases of white swelling before they had been treated by cauterisation —*British Medical Journal*, January 16, 1886

RESECTION OF GANGRENOUS INTESTINE —Nine months ago MR MITCHELL BANKS related to the Medical Society of London a case of strangulated scrotal hernia, in which, on opening the sac, he found several inches of gangrenous intestine The sphacelated bowel was excised and the two ends of intestine were united and returned within the abdomen The patient recovered This case excited some discussion at the meeting at which it was related, and we commented on it We find that, within a few days of the reading of this paper, and before a report of it had crossed the Atlantic, a very similar operation was performed in America, and with an equally successful issue The case is recorded in the current number of the *International Medical Journal*, and was under the care of Dr Clark Stewart, of New York The published report of this case is deficient in many particulars Thus no mention is made of the state of the coil of intestine in the hernia, but only of the diverticulum, except that it is once called "diseased," and it is only from the heading of the report that we infer it to have been gangrenous Nor is there any satisfactory mention made of the state of the coverings of the hernial sac The sequel of the case is also given in a very imperfect manner In spite of these defects, however, the report is valuable, and suggests one or two points for discussion

First, as to the advantage of the operation Dr. Stewart says that out of twenty herniotomies he has seen, gangrenous gut has been found in two instances, and in both the bowel was opened and left *in situ*, "both patients dying early from septicæmia" It was this adverse experience which led him to prefer excision of the intestine when this case presented itself to him We have little doubt that in this particular instance the right line of practice was followed, for at the time of the operation the patient's pulse was only 70, and we are led to infer that there were no local conditions to render such a proceeding particularly difficult or dangerous There appears to have been just that combination of local and constitutional conditions which favors recovery after enterectomy In one particular the steps of the operation differed from the ordinary course Instead of excising a V-shaped piece of mesentery, this peritoneal fold was tied and divided close to and parallel with the bowel The advantage of this plan is that it does not interfere with the blood supply to the bowel on either side or imperil its vitality One of the great dangers attending the excision of a V-shaped piece of mesentery is the occurrence of gangrene in the bowel left behind Where the length of bowel to be removed is not great, the practice pursued by Dr Stewart is undoubtedly the best, and where a greater length of bowel has to be removed, a combination of the two plans might afford the best results, a small V-shaped piece being removed from the central part of the detached mesentery

Still more important inquiries are suggested by the subsequent treatment of the patient Mr Banks used every precaution to secure prolonged rest to the bowel, giving only ice for four days, then for eight days more ice and beef-juice, and the bowels were not relieved until the twenty third day Dr Stewart, on the other hand, gave milk after a few hours, and quickly added alcoholic stimulants and liquid food in "large amounts," while the bowels acted on the sixth day The one case was a man aged 25, the other 68, but this by no means sufficiently explains or justifies such a wide divergence in practice We must confess to being strongly of opinion that the plan carried out by Mr Banks is the better of the two, for it alone secures that rest to the injured parts which is so important in securing their speedy and firm union, and the prevention of extravasation from the intestine, with subsequent peritonitis Dr Stewart's patient seems to have been a very troublesome one to deal with, and all praise is due to the surgeon for the successful issue of the cases, but we believe that if the diet had been more rigorously restricted, and stimulants lessened or withheld altogether, the opiates exhibited would have exerted more power in restraining the peristaltic action of the intestines That, in spite of all these adverse circumstances, the stitches held, and no fæcal extravasations occurred, is a striking testimony to the skill with which the intestinal suture was made and the rapidity with which peritoneal wounds may heal —*The Lancet*, February 6, 1886

HEGAR'S SIGN OF PREGNANCY —In an article on this subject DR EGBERT H GRANDIN, of New York, says During the first six or eight weeks of pregnancy the changes in the uterus are practically limited to the body of the organ The uterine body enlarges, especially in its transverse diameter (antero posteriorly), the muscular substance becomes less dense These changes are simply the result of the hyperæmic condition into which the corpus is thrown and kept by the engrafting of the impregnated ovum As the result of such changes, the uterine body loses its nulliparous pear shape, its contour no longer gradually diminishes as it approaches the uterine neck, the body, on the contrary, bellies out (if I may use the term) over the cervix in all the transverse diameters, in particular, antero posteriorly, and the organ, instead of being pear shaped, resembles very much an old fashioned, fat bellied jug

The above changes in the consistency and shape of the body of the uterus constitute Hégar's sign, and so far, in at least a dozen cases, it has never failed me in early diagnosis The obtaining of this sign requires, of course, a certain expertness in the bimanual palpation, and familiarity with the sensation communicated to the finger by the nulliparous uterus, and the uterus altered pathologically in one or another way I have found, however, in my clinical teaching, but little difficulty in making even inexpert fingers conscious of the change In the vast majority of cases, owing to the normally slight anterior curvature of the uterus, the internal examining finger will note this sign to the best advantage in the anterior cul-de sac Here the finger, instead of following the line of the cervix in a gentle curve up on to the body, is at once conscious of the body swelling out to a greater or lesser degree, according to the date of impregnation, over the cervix, and at the same time, bi manually, the body is faintly boggy, resilient, compressible If such be the condition of affairs detected by the local examination, in the absence of rational history, in the absence of slight softening at the tip of the cervix (which may, if present, mean erosion), and of mammary signs and blue discoloration of the vagina (both of which, if present, may mean ovarian disease), I now unhesitatingly pronounce the patient pregnant The question arises, Are there other conditions which may simulate the above sign? There are two which, I can imagine, might—distended bladder and uterus distended by menstrual blood Neither of these conditions ought, however, to give rise to error, for a necessary prelude to a careful bi manual is evacuation of the bladder by means of the catheter, and retained menstrual blood in the uterus, if not accompanied physically by imperforate hymen or vagina, would necessarily be suggested by the history (no ground for falsifying here) before sufficient had collected to give rise to even faint fluctuation Hyperplasia of the corpus uterus cannot simulate this sign, because in this condition the conjoined touch reveals density, sub involution cannot, because here the uterus is increased in its longitudinal as well as in its transverse diameters, and conjoined touch, while revealing heaviness and softness, does not reveal resiliency and compressibility The markedly anteflexed corpus uteri, hyperæmic from obstructed circulation, is most likely to simulate Hégar's sign, but in case of such distortion the feeling of resiliency and compressibility is also lacking In marked retroversion this sign is likely to fail on account of the difficulty of palpating with ease the uterine body Rectal examination might assist here, but as yet I have had no opportunity to seek for this sign in case of this variety of displacement Compes (*Berlin Klin Wochen*, September 8) who, as far as I am aware, is the only observer who has published observations in regard to Hégar's sign, says that it may always be obtained to better advantage by means of the thumb in the vagina, the index in the rectum, and the other hand externally

He thus, he tells us, reaches the portio vaginalis with his thumb, places his index finger above the sacro uterine ligaments, and when the external hand depresses the fundus, is able, to better advantage, to explore the lower uterine segment I fail to see in what respect this manœuvre is superior to the vagino abdominal method which I practise, aside from my belief that it must be only very exceptionally that the thumb can reach the cervix *per vaginam* while the index is above the insertion of the posterior uterine ligaments *per rectum* —*Med Record*, Feb 27

Permanganate of Potash in Amenorrhœa — In an article on this subject Dr Fordyce Barker says In order more clearly to illustrate my views, I will divide the cases which I have treated with this remedy into three groups, mentioning them in the order of their frequency

First Young ladies between the ages of 14 and 19, who come from the country "to finish their education" Home sickness, entire change of their habits of life and associations, over-tax of their brain-power from their own or their teachers' ambition to accomplish more in a given time than they ought to attempt, not infrequently lead to an arrest of menstruation I see at least ten or fifteen such patients every winter

Second Ladies, both young and married, who suffer severely from seasickness, that have left some European port within a few days of the menstrual period With such, amenorrhœa, of longer or shorter duration, is almost sure to follow I am consulted by at least eight or ten such every year

Third Ladies between 30 and 40, generally married, some of whom have borne children, who rapidly begin to gain flesh, grow stout, while at the same time menstruation decreases in both duration and quantity, until at last it is only a mere pretense This is generally attended with annoying nerve-disturbances, pelvic weight, sometimes hæmorrhoids, and often mental depression from the apprehension of growing old prematurely

I will add, in regard to the third class in my group, that every patient was a resident of this city I presume that every medical man who has been long in practice has met with some such In all these I have known the result from personal interviews—that there has been a satisfactory return of menstruation, although in two cases the use of the remedy was continued for five months In all there has been entire relief of the cerebral and pelvic, and in some of the thoracic, nerve disturbances, cardiac and pulmonary One patient was quite cured of a periodical asthma from which she had suffered monthly for three years

Of course, I never prescribe this agent in cases where the amenorrhœa is due to some grave constitutional disease, nor do I rely on it for the relief of sudden suppression, due to cold, moral shock, or an acute disease In this class I think the pulsatilla, opiates, and local agents, such as fomentations and large hot rectal enemas, are generally successful

In my early experience I found great difficulty in getting the permanganate put up by apothecaries in such a way that patients could take it without great repugnance, and it often produced severe gastric pain, from its rapid decomposition Mr Angelo for a time put it up for me in a peculiar capsule, which did better than anything else, so far as the taste was concerned, and the pain was prevented by swallowing immediately a half-tumblerful of water, not cold Lately I have found two grain tablets do quite as well, if the same quantity of water is swallowed at once —*New York Med Jour*, February 27, 1886

Influence of Milk-Diet on the Excretion of Albumen in Chronic Nephritis—In view of the fact that milk-diet had been emphatically recommended by many observers (Senator, Sparks and Bruce, etc), Dr A S Trubatcheff (*Vratch*, No 46, 1885, p 763) undertook a series of comparative observations on four patients with chronic nephritis (three with the parenchymatous, one with the interstitial form), each of whom received ordinary hospital diet during one period, and either mixed or pure milk-diet during a subsequent period of equal duration The results were as follows 1 An exclusive milk diet invariably led to a marked increase of the daily and percentage amount of albumen in the urine 2 The patient's weight fell considerably, without any marked change in his dropsical state 3 A mixed milk diet also led, in the majority of the cases, to an increase in the daily and percentage amount of the albumen excreted 4 Neither pure nor mixed milk diet produced any marked increase in the amount of urine The author now studies the assimilation of protein by nephritic patients receiving milk diet, which study will enable him to settle the question of "good or harm" of the treatment —*The London Medical Record*, February 15, 1886

The Skin Incision in Herniotomy —Mr C B. Keetley, in a note on this subject, says It has often happened to me to be obliged to prolong the stay in bed of a herniotomy case, for no other reason than that the cutaneous cicatrix has been too tender to bear the pressure of a truss Accordingly, I have laterally incised the superficial structure at some distance external to the ring (whether femoral or inguinal) A retractor easily pulls the skin wound inwards Another advantage of this is, that the wound is removed further away from the pubic region, and therefore more readily kept aseptic To this end, I have also carried a drainage tube from the depth of the wound outwards through a special puncture a couple of inches towards the iliac spine, away from the wound The wound itself can then be completely closed with both buried and cutaneous sutures Another object to be attained by this plan, is that of avoiding the fold of the groin This, in fat people, is simply a kind of transverse gutter, which conducts freely from the pubic region outwards, under the antiseptic dressings, towards the exact site of the ordinary incision for femoral hernia Moreover, a perpendicular incision in this place always tends to gape, and opens widely if the sutures yield before union has taken place In such patients, the incision should be an oblique one, almost parallel with this fold, at all events only approaching it towards its outer end

In the *Liverpool Medico Chirurgical Journal* for January (1886), Mr Rushton Parker is reported to have said "that he made the incision in operations for hernia as far away as possible from the penis and rectum In inguinal hernia, he made the opening directly over the abdominal ring"—*British Medical Journal*, Feb 20, 1886

GERMAIN SEE ON THE TREATMENT OF OBESITY

At the meetings of the Académie de Médecine on September 29 and October 13, 1885, PROFESSOR GERMAIN SEE read an elaborate paper on "The Causes and Physiological Treatment of Obesity, the Therapeutics of Fatty Transformations of the Heart," in which his own ideas are clearly set forth, and the methods and opinions of other writers ably discussed We have already given, in THE JOURNAL of October 24 and 31, 1885, the methods used by Oertel and J Munck, and our London letter, in the issue of December 12, contained a note on the use of taurocholate of soda in the treatment of gouty obesity, as used by Dr Mortimer Granville And in THE JOURNAL of July 18, 1885, Dr Benjamin Lee gave the history of a case of obesity treated by massage

The first indication of fatty infiltration of the heart-muscle, says See, is habitual dyspnœa, due to general muscular feebleness, which incapacitates the patient for any effort, to diminution of the contractile force of the respiratory muscles, and especially to the loss of energy of the heart muscle At the first signs of fatty invasion of the heart the physician should commence treatment Everything which tends to diminish fat tends to increase the motor powers, and everything that augments *the contractility* of the voluntary muscles will at the same time awaken the action of the respiratory and cardiac muscles The fundamental indication, then, is the reduction of fat, consisting more particularly in a special regime, in the determination of the quantity and quality of the fluid ingesta, and in muscular exercise, perhaps, also, certain balneo therapeutic procedures should be added In fine, the medical treatment of cardiac steatosis consists only in combating the functional troubles of the respiration and the circulation

How may we reduce superabundant fat, especially in those cases in which the heart is infiltrated with fat? *Evidently, by the laws of experimental and* practical physiology Physiologists are agreed regarding the "ration of equilibrium," to cover the deficits resulting from continued malassimilation, either during rest or work, or from losses by heat or cold This "ration of equilibrium" is composed of 125 to 135 grammes of albuminous or nitrogenous matter, that is to say, muscular flesh containing 250 to 300 grammes of meat deprived of fat and tendinous parts A part of this may be substituted for by egg-albumen or by fish in bread we find gluten (6 parts in 100), caseine in milk (4 to 100), and leguminose in certain vegetables (10 to 100), these are the nitrogenous principles which may make up the necessary and indispensable quantity of nitrogen. In addition to the nitrogenous principles there should be 84 or 100 grammes of fatty matters, the principal combustibles of the economy Then there should be from 250 to 300 grammes of hydrocarbons, starch or sugar, without taking into account the water necessary to aid in the organic changes, and the mineral elements which enter into the composition of all the liquids and tissues, and the necessary amount of oxygen If this be the "ration of equilibrium" it is necessary to ask, What are the foods that produce obesity? When the quantity of nutriment exceeds the necessity obesity may supervene All foods may become adipogenous, not even excepting the meats and albuminous matter, as they may split up and form fat, and the other constituents of the "ration of equilibrium" may be easily transformed into neutral fats and cause obesity It may be said, then, that there are three sources of fat 1 Albuminates being split up into fat and nitrogenous matters 2 Hydrocarbons taken in certain quantity, easily decomposed 3 From fat itself

Sée takes issue with those, from Pliny to Oertel, who reduce the quantity of fluid ingesta *to a minimum* in the treatment of obesity, claiming that it is not only inhuman but unphysiological and inapplicable to the treatment of the cases under consideration Jurgensen, he says, put himself on a minimum fluid diet, and his temperature went up to 40° C, and "Zuntz asks, with reason, how a dry diet can cause emaciation, it is proved, on the contrary, that by the use of fluids the organism loses vapor of water, and also loses more heat, which causes combustion of fat" All the cases of obesity which he has treated

of grape sugar, or, may we say, to about 240 of hydrocarbons Ebstein's regimen is applicable, says Sée, to cases of cardiac obesity, on condition that it is modified according to the precepts laid down, and especially when gelatines and peptones are added, without any diminution in the fluids Gelatine, gelatinous broths and peptones contribute to the support of the forces, and economize the albuminous matters without transforming them into fat

"COAST DEFENSES AGAINST ASIATIC CHOLERA"

We have recently received from DR JOHN H RAUCH, Secretary of the Illinois State Board of Health, his "Report of an Inspection of the Atlantic and Gulf Quarantines between the St Lawrence and Rio Grande," the result of instructions given to him at the July, 1885, meeting of the State Board of Health to "inspect the methods of quarantine of the Louisiana State Board of Health and their actual operation at the stations below New Orleans, and also to extend his inspection of quarantine methods and regulations to such other ports and places as he may deem necessary in the interests of the public health of the State, with especial referenc to the exclusion of Asiatic cholera and small pox" The Illinois State Board of Health, on receipt of the first information that cholera had again invaded Europe, had taken action to secure a good sanitary condition of the territory under its jurisdiction in case cholera should be introduced, and the inspection was ordered to supplement that action "In the present epoch of quarantine," says the report, "Illinois has a direct interest—chiefly commercial—in the exclusion of yellow fever from the Mississippi Valley, in the exclusion of vaccinally unprotected immigrants at the North Atlantic ports for the protection of her own territory from small pox, and in the exclusion of Asiatic cholera generally, whether it threatens by direct importation from Europe or mediately through the West Indies, Mexico and South America In brief, the State is concerned in the condition of the sanitary coast defenses from the mouth of the St Lawrence to the mouth of the Rio Grande" If the other Sta tion could be ded that they are

on account of the great number of emigrants constantly coming here, and the danger will be increased when the disease reaches the British Islands and those portions of the Continent whence we derive the heaviest portion of our emigration Even if we cannot shut out the cholera entirely it will be a great achievement for sanitary science if its invasion can be postponed and its spread limited, or if we can prevent its obtaining a foot hold here Our quarantine services are as yet imperfect but they have received a great stimulus since 1878, and especially during the past two years, and, imperfect as they, are they give promise of no little success with cholera, judging from the manner in which they have been tested in small-pox and yellow fever "With a sufficient number of National refuge stations, (there should be at least one on the Texas coast and one for New England, in addition to those on the Delaware Bay, Hampton Roads, and Sapelo Sound, and all of them should be as fully equipped as that at Ship Island,) with properly appointed quarantine establishments at the larger ports, and inspection stations at the smaller ones, the entire system to be mutually cooperative, governed by the same general rules and regulations, kept fully informed of public health conditions abroad by consular agents and intelligent medical inspectors when necessary, there would be no reason to apprehend the introduction of cholera or any other foreign pestilence"

In regard to the possibilities of present coast defenses, which he thinks should be under the control of the National Government, Dr Rauch says "Nevertheless, I am more convinced, since completing this inspection, that Asiatic cholera, as well as small-pox and yellow fever, may be effectually excluded from the United States by an intelligent use of the agencies at our command A quarantine of exclusion of these three diseases is now a matter of certainty, depending upon prompt notification of threatened danger, vigilant supervision over commercial intercourse with infected localities, inspection of all immigrants and the enforcement of their vaccinal protection, sanitation and purification of infected vessels and cargoes, isolation of those sick with these diseases, the surveillance of suspects during the periods of incubation, and the employment of other well defined preventive and precautionary measures which now constitute the best modern sanitary practice as applied to maritime quarantine" He well points out the different conditions which obtain in this country and in Europe regarding the enforcement of quarantine measures "There, cordons nd quarantines mean privation, misery and suffering, have been cured by the albumino fatty régime, and so far from being put on a restricted fluid diet they have had more fluid than usual, particularly aromatic cold drinks, such as tea in the morning, and slightly alcoholized cold drinks at dinner. "Digestion is thus aided, and not interfered with, as was stated at the German Congress at Wiesbaden. The fat, so rebellious to the stomach, is precipitated into the intestine, where it is emulsified, while the albuminates are peptonized. But this is not all, if water favor digestion it also hastens denutrition." See bases this assertion on the experiments of Falk, Bischoff, Foster, Genth and others on the elimination of urea after the ingestion of certain quantities of water. Water, then, he says, is not only an eliminator of pre-existing urea, but a means of increasing denutrition, and diminution of the amount of fluid taken has no *raison d'être*. He claims that water, especially when cold and aromatized, has the advantage of precipitating the alimentary mass into the intestine, where peptonization, emulsion and transformation are facilitated, but it is to be noted that the temperature of the water plays a considerable part. It was supposed for a long time that water was principally absorbed by the mucous membrane of the stomach, but that this was an error was shown by Béclard. He showed that fresh water, taken when the stomach is empty, soon goes into the intestine—that is to say, within a few minutes. It enters the circulation from the intestines, but it does not stay there, nor does it ever cause serous plethora or hydræmia, as was shown by Denis, Magendie and Nasse. But with regard to the differences of opinion as to the part played by fluids in the causation and treatment of obesity, we shall have something to say in the next issue of THE JOURNAL, as Oertel has brought an immense mass of fact and experimentation to bear on this question.

In regard to the medical treatment of obesity Sée dismisses the venesection of the sixteenth century with the remark that blood letting tends to produce anæmia and deposition of fat, as has been shown by Vulpian and Dechambre. The true medicinal treatment consists, he says, in the administration of iodides, alkalines, and purgatives. It is to be remarked that the conjoined administration of iodine and alkalines is very favorable to iodism and to great emaciation. In large doses, kept up for some time, we know that it acts unfavorably on the lymphatic, thyroid and mammary glands, and on the genital organs of man, and it is not very uncommon to see the menstrual functions accentuated when the female is under the influence of iodine. Iodine, however, is a drug to be used with extreme caution in these cases, in view of the fact that anorexia and dyspepsia are so frequently caused by it. Since the experiments of Chevreul, in 1825, and of Mialhe and Liebig, in 1850, the alkaline carbonates have been thought to be oxydants of great power, but it has been shown by Munck, Séverin, and Seegen that they cause decrease in the amount of urea eliminated. But Scheremeljewski, in order to show the action of alkaline waters on the combustion of fat, injected lactate of soda into a rabbit; he found that it caused a slightly increased elimination of carbonic acid and a more marked absorption of oxygen. It should be remembered, however, that lactate of soda itself may, by a transformation into carbonate of soda, produce a slight excess in the amount of carbonic acid exhaled and oxygen absorbed, and there is nothing to show that carbonic acid is due to the combustion of fat. We only know, then, that the alkaline waters are useful, but we do not know why; and so long as clinical experience shows that they are we should use them, with suppression of alcoholic fluids, of starches, reduction of food, aided by muscular exercise and oxygenation by living in the open air as much as possible. With regard to the purgative waters, it is only necessary to say that they seem to be superior to the purely alkaline waters. We need not mention the purgative waters of Europe, as this country is sufficiently rich in those waters to enable one to make a large choice.

We have already said that Sée has used the albumino fatty regimen in all the cases of obesity treated by him. This is a modification of the system of Ebstein, which allows 60, 80, or even 100 grammes of fat, butter or lard, a day. See adds gelatinous matter and gives a large quantity of fluid. Fatty matter of which the fat cells are not imprisoned in a too solid connective tissue is easily digested, and Ebstein has even cured cases of dyspepsia with the above named quantity of butter or lard (his own case among others). Ebstein says that fat diminishes the hunger and thirst, and limits the quantity of solid and liquid nourishment. Sée replies that it undoubtedly lessens the sensation of hunger and thirst, but he thinks that the use of fat enables the organism to take up the albuminates more completely, without which they are taken in excessive quantities, and this is a most efficacious means of economizing, as has been shown by Voit. It has been shown by Unna that on the albumino fatty diet the fat of the heart and muscles is the first to disappear, and that the subcutaneous fat disappears afterwards. Rubner has shown that 100 grammes of fat are equal, from a dynamic point of view, to 211 of albumen, 232 of starch, and 256 of grape sugar, or, may we say, to about 240 of hydrocarbons Ebstein's regimen is applicable, says Sée, to cases of cardiac obesity, on condition that it is modified according to the precepts laid down, and especially when gelatines and peptones are added, without any diminution in the fluids Gelatine, gelatinous broths and peptones contribute to the support of the forces, and economize the albuminous matters without transforming them into fat

"COAST DEFENSES AGAINST ASIATIC CHOLERA"

We have recently received from Dr John H Rauch, Secretary of the Illinois State Board of Health, his "Report of an Inspection of the Atlantic and Gulf Quarantines between the St Lawrence and Rio Grande," the result of instructions given to him at the July, 1885, meeting of the State Board of Health to "inspect the methods of quarantine of the Louisiana State Board of Health and their actual operation at the stations below New Orleans, and also to extend his inspection of quarantine methods and regulations to such other ports and places as he may deem necessary in the interests of the public health of the State, with especial referenc to the exclusion of Asiatic cholera and small pox" The Illinois State Board of Health, on receipt of the first information that cholera had again invaded Europe, had taken action to secure a good sanitary condition of the territory under its jurisdiction in case cholera should be introduced, and the inspection was ordered to supplement that action "In the present epoch of quarantine," says the report, "Illinois has a direct interest—chiefly commercial—in the exclusion of yellow fever from the Mississippi Valley, in the exclusion of vaccinally unprotected immigrants at the North Atlantic ports for the protection of her own territory from small pox, and in the exclusion of Asiatic cholera generally, whether it threatens by direct importation from Europe or mediately through the West Indies, Mexico and South America In brief, the State is concerned in the condition of the sanitary coast defenses from the mouth of the St Lawrence to the mouth of the Rio Grande" If the other States in the Union could be persuaded that they are as much interested in keeping out infectious and contagious diseases as Illinois the health organization of the country would certainly be much more perfect

In regard to the present status of quarantine and the prospects for keeping cholera from the country, Dr Rauch reminds us that this country is not yet free from danger of invasion because there is a temporary cessation of the disease in Europe The country is in danger as long as there is any cholera in Europe, on account of the great number of emigrants constantly coming here, and the danger will be increased when the disease reaches the British Islands and those portions of the Continent whence we derive the heaviest portion of our emigration Even if we cannot shut out the cholera entirely it will be a great achievement for sanitary science if its invasion can be postponed and its spread limited, or if we can prevent its obtaining a foot hold here Our quarantine services are as yet imperfect but they have received a great stimulus since 1878, and especially during the past two years, and, imperfect as they are they give promise of no little success with cholera, judging from the manner in which they have been tested in small-pox and yellow fever "With a sufficient number of National refuge stations, (there should be at least one on the Texas coast and one for New England, in addition to those on the Delaware Bay, Hampton Roads, and Sapelo Sound, and all of them should be as fully equipped as that at Ship Island,) with properly appointed quarantine establishments at the larger ports, and inspection stations at the smaller ones, the entire system to be mutually cooperative, governed by the same general rules and regulations, kept fully informed of public health conditions abroad by consular agents and intelligent medical inspectors when necessary, there would be no reason to apprehend the introduction of cholera or any other foreign pestilence"

In regard to the possibilities of present coast defenses, which he thinks should be under the control of the National Government, Dr Rauch says "Nevertheless, I am more convinced, since completing this inspection, that Asiatic cholera, as well as small-pox and yellow fever, may be effectually excluded from the United States by an intelligent use of the agencies at our command A quarantine of exclusion of these three diseases is now a matter of certainty, depending upon prompt notification of threatened danger, vigilant supervision over commercial intercourse with infected localities, inspection of all immigrants and the enforcement of their vaccinal protection, sanitation and purification of infected vessels and cargoes, isolation of those sick with these diseases, the surveillance of suspects during the periods of incubation, and the employment of other well defined preventive and precautionary measures which now constitute the best modern sanitary practice as applied to maritime quarantine" He well points out the different conditions which obtain in this country and in Europe regarding the enforcement of quarantine measures "There, cordons and quarantines mean privation, misery and suffering, and, ultimately, starvation Here, the Nation could exist unaffected in all her material interests by a quarantine whose period of detention is limited to the time necessary to destroy contagion through the rapid processes of modern disinfection and sanitation "

By far the greater part of the report is taken up with an account of the location of quarantine stations, their equipment, powers and authority, rules regulations, methods, etc , from Canada to Texas, most convenient information for those interested in the subject, and from which it is easy to form comparisons and to obtain information regarding the stations and the quarantine regulations of the different States In view of the fact that cholera was introduced into this country via the St Lawrence river in 1832, Dr Rauch makes a number of valuable suggestions in regard to the quarantine station at Grosse Island, 29 miles below Quebec, which would render the service more efficient and be in the interests of commerce Regarding the service at Boston he says "The access of cholera is hardly likely to occur During this period (nineteen years) I have been able to trace small pox cases to Boston very rarely, and none for several years recently The mothods pursued at this port demonstrate that the disease may be excluded " The *quarantine facilities of New* Haven, the most important port of Connecticut, are described as not entirely satisfactory With reference to the exclusion of cholera and small pox from the *port of New York he says "With proper vigilance*, the service should suffice to prevent either of these diseases from obtaining access to the country through this avenue But the entire system is hampered by a vicious financial policy which is, in effect, a farming-out of the service New York may exclude cholera under her present systems, but more confidence would be reposed in the result if less were demanded of professional ability, personal integrity and executive firmness in the health officer, and if the system were freed from influences which are most deprecated by those who, without prejudice, best understand them "

In the quarantine of Philadelphia, the only port of Pennsylvania, "there has been practically little change in the equipments or methods since 1818 There are none of the modern appliances for disinfection of vessels or cargo No attention is paid to the vaccinal status of immigrants unless small pox is discovered on a vessel, and, as a natural consequence, the disease has frequently been introduced into the interior through this port " At the U S Quarantine Station at Delaware Breakwater, there is no serviceable inspection boat, and no arrangements for disinfecting cargoes or clothing The quarantine season at Baltimore extends from May 1 to October 1 "No attention is paid to the vaccinal protection of immigrants, unless small-pox is discovered on a vessel, and owing to this neglect repeated introductions of the disease into the interior have occurred through this port There are no facilities as yet provided for the discharge and disinfection of cargo from an infected vessel," and Dr Rauch suggests, in the present emergency, the advisability of requiring vessels to submit to inspection by the Government service at Cape Charles The quarantine facilities of Wilmington, the only important quarantine port of North Carolina, are inadequate, and the means of disinfection primitive "The quarantine hospital was burned two years ago, and the State has not rebuilt it " Dr J T McFarland, Health Officer of Savannah, says 'I cannot refrain from an expression of condemnation and protest against the unreliability of the ordinary bills of health issued by some consuls of the United States It is a frequent occurrence that clean bills of health are issued by them at ports where deadly epidemic diseases are prevailing I know positively that steamships, from districts of Spain affected terribly with cholera, have been admitted into one of the largest ports of the United States, during this season, without the slightest attempt at fumigation of the clothing of the seamen, or cleansing of vessels, the statement being made to me in official correspondence, that as no sickness had occurred during the voyage, it was deemed unnecessary to use any precautions, and that this would be the line of action pursued in the future at that port " Dr Rauch also calls attention to the worthlessness of most consular bills of health

Taken altogether, this Report, of 31 pages, contains a very large amount of important information, and should certainly be in the hands of every health officer in the country Dr Joseph Holt's description of the manner in which disinfection is carried out at Pas a L'Outre, should be studied by all quarantine officers His report and that of Dr Swearingen, of Texas, are very complete It is to be regretted that no information could be obtained from Key West and some other places

WHAT'S IN A NAME?

Are not all the State and local Societies in the several States and Territories of the Union, that have adopted the National Code of Ethics, and consequently entitled to send delegates to the American Medical Association, actual Branches of the National organization? In the two preceding issues we have endeavored to explain the principle on which the American Medical Association was founded, its capability, when properly applied, of developing a complete organization of the regular profession in the United States, from city, county, and district societies to State Societies in each State, and from the State Societies to the National Association as the general head. The State Societies were formed by delegates from the more local organizations, and the National Association by delegates from the State Societies, the whole governed by one Code of Medical Ethics, and the governing power in all the State and National Organizations consists of delegates annually elected on a uniform ratio representation. We pointed out some imperfections in the application of the principles in the original plan adopted, and the subsequent correction of these by successive alterations or amendments as experience demonstrated their existence, and the steady progress of the organization until, at the present time, it pervades every State and inhabited Territory in our country.

With few exceptions the State Societies are sustained by delegates from the county and district societies, and the National Association by delegates from the State Societies and such county and district societies as are recognized by representation in their respective State Societies, thus making the State and local societies not only *Branches* in the true sense of the word, but *Branches* without which the National Organization, as the head, would have no existence. True, we have been calling them *affiliated* societies instead of calling them *Branches* after the British custom. Indeed, the relation between our State and local societies affiliated by a uniform ratio of delegates, with the American Medical Association, is much closer and more important than is the relation between the British Association and its Branches. While each Branch of the British Association is allowed to regulate its own affairs so long as it makes no regulation conflicting with the laws of the parent body, and to elect one member of the governing *Council*, each Branch or affiliated society of the American Medical Association is permitted to regulate its own affairs, subject only to the National Code of Medical Ethics, and instead of electing one member of the governing council it elects one delegate to the parent Association for every ten of its regular members, who constitute a part of the governing body.

But it is claimed that inasmuch as all members of the Branches of the British Association are also members of the parent Association, and thereby increase both the numerical strength and income of the latter, the same result would be reached by making all members of the Branches of the American Association also members of the latter body. The fact seems not yet generally known, as we infer from the statements of some of our correspondents, that by the amendment of the constitution of the American Medical Association, proposed in 1882 and finally adopted in 1884, any member of a State, county, district, or other local society in affiliation with the general organization can, at any time, become a Permanent Member of the American Medical Association by simply sending a certificate of his membership and good standing in the society to which he belongs, with the amount of the annual dues, five dollars, to the Treasurer of the National Association. Indeed, by this provision of the constitution every local or State Society entitled to representation in the American Association can make its entire membership Permanent Members of that Association whenever it chooses, and they will retain such membership so long as they pay the annual dues and remain in good standing in the profession, and will enjoy all the privileges that belong to Permanent Members constituted in any other way. It is doubtful whether a more simple or practicable method could be devised for increasing the permanent membership of the National Association than this. It leaves the matter to the voluntary choice of every member of the regular profession who is willing to sustain the local medical organizations of his own State, to become a member of the National Association without the expense and loss of time incurred by attending its annual meetings.

We think the appointment of a judicious committee to report on the subject, as suggested by "Branch," in his last letter, in THE JOURNAL of March 6, would be desirable and productive of good, if for no other reason than that it would make the actual provisions of the constitution of the National Association better understood by the profession generally.

DEATH OF DR. WILLIAM E. JOHNSTON.—Our foreign mails bring the news of the death of this well-known American physician, who died in Paris, where he had lived for twenty years, on February 14. He went to Europe at the close of the Civil War, and in 1866 obtained permission to practice medicine on his American degree. He was officially attached to the American Legation in Paris, and rendered great service during the siege of Paris, for which he was made Chevalier of the Legion of Honor in 1876.

SOCIETY PROCEEDINGS

CHICAGO MEDICAL SOCIETY

Stated Meeting, March 1st, 1886

THE PRESIDENT, C T PARKES, M D, IN THE CHAIR

DR P C JENSEN read the first paper of the evening, entitled

DIGESTION AND DYSPEPSIA

The author entered into an elaborate discussion of the physiological processes of digestion, the departure from normal, and the treatment of gastritis, ulcer of stomach and atonic and nervous dyspepsia Owing to the length of the paper the author was obliged to omit a large portion it

DR J FRANK thought that in the diagnosis of stomach disease pain under the left shoulder would not be a pathognomonic sign in case any cardiac trouble co existed It is well known that patients with cardiac disease complain of pain under the left shoulder He had found that the majority of cases of dyspepsia are due to dilatation of the stomach and diseases of the pancreas

DR C C P SILVA spoke of the omission, among the cases enumerated by the paper, of that common form of indigestion due to the excessive use of tea or coffee, especially when the tea or coffee has been boiled for a long time and drank after all the aromatic principles have been evaporated and there is left only the tannic acid, which precipitates pepsin This is one of the most frequent causes of indigestion with ladies who abstain from cooking much and use only tea which is not freshly made, with bread and butter, taking such a lunch frequently

DR JENSEN, in concluding the discussion, said that he had found that in dyspeptic, as well as heart troubles, there is pain under the left shoulder It is a symptom of dyspepsia when other affections can be excluded As to dilatation of the stomach, it is often a cause of dyspepsia, and he had found it especially prevalent with beer drinkers who drink beer in large quantities, ten to twenty glasses a day As to disease of the pancreas being a cause of dyspepsia, it is a very obscure organ and it is difficult to diagnosticate disease in it In regard to long drawn tea and coffee being an influential factor in the production of dyspepsia, he had observed that drinking too much liquid of any kind with the food has a very deleterious effect upon the digestion, reducing the quality of the gastric secretion, and thereby hindering the proper digestion of the food

DR J H ETHERIDGE read a report of

TWO UNIQUE CASES OF VESICO VAGINAL FISTULA

In the first case the bladder appeared to be torn across from side to side about 1½ inches from the meatus urinarius, and the "flap" thus liberated was hermetically sealed to the posterior wall of the vagina The cervix uteri was completely surrounded with adventitious connective tissue, in whose meshes was retained menstrual fluid

In the second case, following a very protracted, severe labor, wherein the forceps had been fruitlessly used, and twelve hours later delivery was allowed to be spontaneously accomplished, the most extraordinary results ensued *The right ovary and uterus had completely disappeared by sloughing* The left ovary remained

THE PRESIDENT said he thought it a well established fact that there is a possibility of an accidental expulsion of the uterus and its appendages occurring in connection with labor During the past year there has been quite a discussion on the question of whether it is possible for such a thing to happen, and so far as the extract published in the *British Medical Journal* goes, it seems to prove that cases do occur in which, as far as we know, no interference with forceps or otherwise was made, and yet there was extrusion of the uterus and its appendages, and sufficient constriction thereof to produce sloughing and entire loss of these organs

DR F M WELLER remembered a case in which rupture of the bladder into the vagina occurred, and the only cause to be observed was some gravel stones found in the bladder He had no doubt that they were the result of vesico vaginal fistula

DR R TILLEY inquired if he had asked the physicians who attended these cases if forceps were used?

DR ETHRIDGE knew nothing of the antecedent histories of these patients The first was a Bohemian woman who spoke German indifferently, and it was difficult to get her history The second patient was an American-born girl, and she gave a pretty succinct history of her experience She was in labor forty eight hours, consultation being called at the end of thirty six Instruments were tried but failed to deliver her, and the physicians gave it up and went home Finally pains came on and expulsion of the pelvic contents took place

DR H P NEWMAN read a report of

A CASE OF RUPTURED OVARIAN CYST, WITH SPECIMENS

Mary H, unmarried, occupation, housework, age, 25, Norwegian Since her first menstruation at 13 years of age the menses have been regular but scanty, accompanied by severe pain, necessitating her lying in bed the first day of each period After coming to this country, four years ago, she seemed to suffer less in this respect, and while not strong, enjoyed a fair degree of health In September of last year she had a mild attack of typhoid fever, convalescing at the end of the second week During October she gained rapidly in flesh, and experienced less pain than usual at the menstrual molimen, as he afterward learned In the second week of November following she was taken ill with peritonitis It was during this attack, which was of several weeks' duration in the subacute and localized form, that his attention was first called to any abnormal condition of the pelvic organs The tenderness of the abdomen and pelvic viscera rendered a thorough exploration impossible, and it was not until January that a satisfactory examination was made

The patient first came to his office January 25th, when he found a tumor extending upward and a little to the right of the median line, from the lesser pelvic basin to midway between umbilicus and symphisis pubis, and corresponding in size and general outline to the gravid uterus at the fourth month Further investigation revealed fluctuation in the tumor, also that it was detached from the uterus, the latter being crowded to the left and back into the hollow of the sacrum Although the fluid contents were not examined the growth was pronounced a probable cyst of the right ovary, and the patient so advised To any operative procedure the patient demurred, but promised to consider the matter and report at his office the following week Nothing was heard from her until February 3d, ten days later, when he was called to her house at about 6 P M He found the patient up, but complaining of pain and soreness of the abdomen, which was slightly tympanitic Temperature 99½°, pulse slightly accelerated With the use of an opiate and hot fomentations, the following morning he found her free from pain, with less tenderness over the abdomen, and no tympanitis Pulse and temperature normal He enjoined rest in bed, and directed that he should be called in case of further trouble

On the night of February 6th he was summoned by the message that the patient was very low, and not expected to live through the night He found the patient at 11 P M bolstered up in a chair, in a crouching attitude, with the thighs flexed upon the abdomen The countenance bore such a pinched and anxious expression as gave striking evidence of grave peril He was informed that following his visit on Thursday the patient had grown quite comfortable and free from pain, and contrary to his instructions sat up a large share of Friday In the evening, while reading a letter, still sitting up in bed, she suddenly cried out that something had broken inside the abdomen She suffered great distress, and was very much prostrated until 2 o'clock A M, when she became more quiet From this time she grew weaker, and had a very "bad feeling," as she described it, vomiting at intervals during the day, but suffering no particular pain He was not called until late at night, twenty-four hours after the accident related He found a rapid, feeble pulse of 140, skin moist, extremities cool, temperature 99° F, bowels tympanitic, but no pain, and little tenderness She had passed no urine since the preceding night, and hardly a tablespoonful of dark fluid could be obtained by the catheter A digital and bimanual examination revealed little or no change in the consistency and general outline of the tumor, as far as could be ascertained through the distended abdomen

The gravity of the situation was explained to the friends, and an exploratory operation insisted upon as the only hope As immediate consent could not be obtained he advised a consultation He therefore met Dr A B Strong at ten o'clock that morning Through the stimulants which had been freely administered during the night the condition of the woman remained much the same Suppression of the urine was still a marked symptom, abdominal tympanitis somewhat increased, temperature normal The possibility of ruptured pelvic abcess, or intestinal perforation from fæcal impaction, was considered, the doctor concurring with me in urging an immediate operation As soon as arrangements could be made the patient was etherized and placed upon a table He requested Dr Strong to perform the operation The incision through the abdominal wall was about three inches in length, midway between umbilicus and pubis in the median line As soon as the peritoneal sac was opened there poured forth about three pints of purulent fluid When this had been washed away, the tumor was readily recognized filling the entire hypogastrium, its peritoneal surface engorged and discolored by the existing inflammation. Owing to the extensive adhesions, it became necessary to carry the original incision upward and through the umbilicus to a point two inches beyond, and downward to the symphisis The fundus of the tumor was firmly attached along the under surface of the mesentery, making it necessary to ligate before removal, and, on closer inspection a recently torn adhesion was observed, exposing a minute opening in the thinned wall of the sac, through which was oozing the purulent contents In this connection it should be said that since her former attack of peritonitis, the patient had complained of increasing pain on resuming the recumbent posture, a fact now easily accounted for by the extent and nature of the adhesions, which must have been thereby put upon the stretch It is also probable that while sitting up in bed, movements of the body or abdominal viscera together with the softening of adhesions by recent inflammation, had produced the rupture here found, and so perceptible to the patient The complete separation of the remaining adhesions, and the removal of its growth with the right ovary and fallopian tube, was accomplished The pedicle was tied with waxed silk, the ligature cut short and left within the pelvic cavity All torn surfaces inclined to bleed were cauterized with a hot iron The peritoneal cavity was washed out with hot water, dried with clean sponges, the wound closed, leaving a drainage tube in its lower angle, and the abdomen covered with antiseptic dressings

Notwithstanding the free use of stimulants previously to the operation, and hypodermic injections of brandy toward its completion, within the next hour the woman's pulse became hardly perceptible at the wrist, and her immediate condition critical in the extreme After the use of further injections of whiskey and ammonia, and the application of bottles of hot water to the extremities, the patient rallied slightly and recognized those about her From nine o'clock in the evening, however, she gradually sank, and died at eleven P M The abdomen was opened the next morning by Dr Strong and the writer Though covered with recent exudations of lymph, the peritoneal surfaces were of a better color, nor had bleeding occurred from any of the points of detachment.

The tumor as here presented is a unilocular, dermoid cyst, its purulent contents, about a pint and a half, resembling very much the fluid found in the pelvic cavity It also contained a mass of fatty substance bound together with a quantity of hair The right fallopian tube here attached, was uniformly enlarged and held a number of drops of pus The left ovary, which was removed post mortem, also contained a few small cysts. The uterus was normal both in size and appearance.

The points of interest are first, the disparity between the temperature noted and the extreme inflammatory changes in the peritoneal cavity, second, the difficulty in differentiating between rupture of this cyst, and a possible pelvic abscess, also the resemblance of the symptoms to those observed in a case of twisted pedicle, as reported to the society by our President, Dr. Parkes, at a recent meeting, and third, the liability of rupture of ovarian cysts even of small size, where inflammation occurs, constitutes additional arguments in favor of early operation.

DR. A. B. STRONG said he believed it was generally supposed by the profession that peritonitis is always by an elevation of temperature as indicated by the thermometer. He had recently seen a case in which a large quantity of pus was removed by section from the abdomen of a boy, in which the thermometer did not indicate any rise of temperature. These two cases seem to show that in purulent peritonitis the temperature is not always a practical aid in diagnosis, unless in a negative way.

THE PRESIDENT was inclined to think from some of the symptoms reported that this was a case of twisted pedicle, and that the rupture was caused by the twisting of the pedicle, which is quite often the result of the subsequent distension of the cyst walls, if it is weak at any point it ruptures. Darkness in color is one noticeable change found in twisted pedicle, and if this was not a case of twisting, there was great resemblance in the symptoms and those of cases he had seen, viz., rapid distension of the abdomen, increased temperature, symptoms of peritonitis, and suppression of urine. In case the ruptured cyst was dependent upon twisted pedicle it might account for the separation of the adhesion, which was found. The mere fact of the movement of the body which was advised against might have precipitated a turn of the tumor upon itself, which led to the rupture by a diffusion of blood. He thought it a very interesting case and one calling attention to the necessity of insisting upon early interference in all cases where there is a supposed tumor of the abdomen, accompanied by the symptoms mentioned. And where the operation is done early there is very little difference in the fatality as compared with the operation done without peritonitis being present.

DR. NEWMAN said, in conclusion, that he did not think twisted pedicle was present in this case. The adhesions of the upper part and sides of the tumor, were of such a nature that there could be but slight twisting of the base on the pedicle, and if it had occurred as a factor in separating the adhesions it must have returned to its normal position again, for the tumor when found, occupied its usual position.

DR. STRONG said he was sure the pedicle was not twisted. There were two points of attachment to the tumor, one adhering to the base of the mesentery on the right side, the other to the sigmoid flexure, both old adhesions, and the points of attachment so located that it would be impossible for the pedicle to be twisted.

THE PRESIDENT wished to know how the dark color was accounted for.

DR. STRONG said that it looked at first very much like a uterine tumor, being thick and vascular. It was a light mahogany color, but was not such a color as is found in a strangulated gut.

DR. J. H. ETHERIDGE said, in reference to the lack of correspondence between the temperature as indicated by the thermometer, and a high degree of inflammation, that the temperature will often be found in cases of peritonitis to be sub normal. In cases of gonorrhoea in the female, complicated by pelvic peritonitis, physicians are often misled by the fact that the inflammation which produces great pain in the abdomen is not accompanied by a temperature which would lead him to suppose that peritonitis is present, thus causing him to erroneously rule out the possibility of there being peritonitis.

DR. G. W. WEBSTER exhibited a convenient

CASE OF ANTIDOTES FOR POISONS, WITH STOMACH TUBE.

He said that in his limited experience in the treatment of patients who had taken poison either accidentally or otherwise, he had often found it difficult to procure the proper antidotes quickly enough and in a suitable form. It was this that led him to devise this case, intending at the time to have only one made for his own use. The case itself contains a pamphlet concerning poisons and their antidotes, a stomach tube, and the following drugs ether, ammonia carbonate, nitrate of amyl, apomorphia, sulphate of atropia, brandy, camphor, animal charcoal, chloral hydrate, chloroform, digitaline, dialyzed iron, sulphate of iron, tr. of chloride of iron, mucilage, calcined magnesia, sulphate of morphia, iodide of potassium, liquor potassæ, acetate of strychnia, chloride of sodium, sulphuric acid, tannic acid, sulphate of zinc. The atropia, morphia, apomorphia, strychnia and digitaline have been made up in compressed tablets and combined with soda so that they can be given hypodermically.

DR. J. FRANK exhibited a specimen of

DEGENERATED RIGHT KIDNEY,

with a brief history of the case. Thirteen weeks ago, lithotrity was attempted on a man sixty nine years old. The lithotrite broke, and the next day lithotomy was performed. The patient did well for about three weeks when he seemed to fail again, and pus appeared in the urine. Then he got better, and the pus disappeared. But a relapse came and he died. During the time he was voiding pus, Dr. Frank had made microscopic examinations to find casts, but was unsuccessful. There was total degeneration of the medulary substance of the kidney exhibited, while the other one was full of renal calculi.

THE PRESIDENT remarked that the degeneration of the kidney was so great that tube cast formation would be impossible.

DR. R. TILLEY exhibited a sample of

LANOLIN

which he obtained through favor from Frazer & Co., of New York. He said lanolin has lately been brought prominently before the medical public by the researches of Prof Oscar Liebreich, of Berlin, and its clinical applications by Liebreich and others The substance exhibited, you will observe, is of a yellowish brown color, and of a plastic consistency The upper layer is darker than that immediately beneath Its odor is slight, but *sui generis* Liebreich says it should smell like wool It is found in practically all the keratine tissues of the animal economy, but the commercial article is undoubtedly obtained from wool The sample he supposed to be a mixture of equal parts of pure lanolin and water Liebreich calls it a cholesterin fat, that is, a substance composed of fatty acid and cholesterin The more commonly recognized animal fats being, of course, compounds of fatty acids and glycerine He promises later to give us its exact chemical composition The special point of interest about it to us as physicians, is, that it seems to be absorbed by the integument with much greater facility than the substances now in general use as bases for ointments In the *British Medical Journal* of Feb 13, 1886, a number of formulæ are given, being so far, the result of Prof Liebreich's observations as to the most convenient method of associating it with other substances He there refers to several clinical cases of interest, psoriasis, favus, and eczema He regards it as an excellent base for blue ointment He claims that when a small quantity of a sublimate ointment of 1 in 1000 made with lanolin is rubbed on the skin, that in a few minutes the characteristic metallic taste of mercury appears in the mouth, and from this and other observations, concludes that all toxic agents should be used, when associated with lanolin, with great caution

CHICAGO GYNÆCOLOGICAL SOCIETY

Stated Meeting, Friday, January 15, 1886

THE PRESIDENT, DANIEL T NELSON, M D, IN THE CHAIR

W W JAGGARD, M D, EDITOR

DR CHARLES WARRINGTON EARLE read a paper entitled

THE WATERY DISCHARGES OF PREGNANT WOMEN

Case 1 —Mrs F K consulted me for a profuse watery discharge which had taken place several times during her pregnancy, commencing at the third month She was the mother of three children, and had always been free from any marked pelvic disease The first discharge was clear and watery, and she estimates the quantity at about two quarts This came away in a gush, most of it being discharged at once, although there was a slight loss for some days thereafter At first it was thin and clear, then slightly thicker, of the color of weak coffee These discharges seemed to occur every two or three weeks, and were frequently attended with considerable pain There was a decided diminution in the size of her abdomen after each discharge

On October 30th I found her in great pain, and an examination demonstrated that the fœtus was very low in the pelvis and apparently not surrounded with any liquor amnii The os uteri was neither soft nor dilated She was ordered anodynes and to remain in bed On the 7th of November I again saw her, and found she had been having more or less pains since my previous visit There was no dilatation Two days after, however, she was delivered, her gestation having lasted about two hundred days The child lived about one hour She made a good recovery and resumed her place in her family in the course of two weeks

Case 2 —Mrs M, 27 years old, in her ninth pregnancy At the end of five months she commenced to have a flow of fluid which continued until the end of the seventh month, when she gave birth to twins, one living and the other dead There was no escape of liquor amnii at her confinement The same lady in her eleventh pregnancy commenced to lose fluid at the end of the seventh month, which continued until the completion of the full term, when she gave birth to a healthy child She had what her attendants called a dry labor

Case 3 —Mrs D W R, aged 31, the mother of nine children, has been pregnant since July 1st, 1885 On November 20th she said to a friend who was at her bedside that she was flowing, and asked to be supplied with a napkin A sheet folded and placed under the patient was thoroughly saturated with fluid, the discharge being equal, probably, to about two pints She had severe pains, simulating those of labor, lasting a few hours On December 15 she had a similar discharge The future of this case is yet to be decided

Frequency —These cases evidently take place with more frequency than we have, up to this time, supposed, but the older obstetric authors have noticed peculiarities of this kind, and given very fair descriptions of the complication

Smellie says (page 177, Vol II) "Dribbling of fluid may go on for weeks, but a sudden gush is invariably followed by parturition, the longest interval between a sudden gush and labor being seven days" In this he is certainly mistaken, as the history of many recorded cases and some of mine will demonstrate

Denman, 1815, says "Instances have been recorded in which the waters of the ovum are said to have been voided as early as the sixth month of pregnancy without prejudice either to the child or to the mother The truth of these reports seems to be doubtful, because where the membranes are intentionally broken, the action of the uterus never fails to come on A few cases of this kind, somewhat similar, have occurred to me A discharge of colorless fluid takes place, daily, from the vagina for several months preceding labor, which is due to the rupture of some lymphatic Such labors are usually premature and the fœtus small" The same authority also cites a case where, after the delivery of the placenta, several pints of lymph were discharged

Burns, 1822, page 238, says that the discharges of watery fluid from the vagina are not infrequent, and generally depend upon the secretion of glands about the cervix, the rupture of lymphatics, or from fluid collected between the chorion and amnion, or water from blighted ovum in the case of twins

Dr Pentland relates a case in which coughing produced a discharge, the water being discharged at the fourth month, but labor only occurred at full term

Merriman, in his work entitled "Difficult Parturition," 1826, relates the case of a lady—six months pregnant—from whom a profuse, watery discharge occurred She summoned a physician, who assured her that if pains came on she would soon be delivered She continued, however, to the end of pregnancy, having a profuse discharge each day At full term she was delivered, her attending physician rupturing a bag of waters, which appeared in no way different from usual cases No opening was discoverable in either the placenta or the membranes, and he concluded that the discharge must have come from the outside of the membranes

Chailly, edited by Bedford, 1844, gives a rather full account of hydrorrhœa, the description not being different from those I have already related He says, however, that these discharges are more frequent than are generally supposed, but makes the erroneous statement that in nearly all these cases pregnancy is carried along to its full term

Nearly all modern authors devote a short section to the consideration of this subject, giving different names, as their ideas of its origin and pathology are different

Three separate and pathological conditions seem to be, in many cases, confounded, and I see no way by which a differentiation can be made

1st A discharge of the liquor amnii
2d Discharges from increased glandular action
3d, A possible collection of fluid between or outside of the membranes, and its irregular evacuation

In my teachings I have been in the habit of speaking of hydrorrhœa, but never, up to a few months ago, had I seen a marked case A study of this case with others collected from my own experience, and the perusal of the article written by Dr Thomas C Smith, of Washington, D C, which appeared in the *American Journal of Obstetrics*, in May, has caused me to go over the subject carefully and to present what I can obtain from the authorities in regard to these peculiar discharges Great numbers of cases have been recorded, but no one, up to this time, has demonstrated conclusively the source of the flow

The etiology of these discharges has been the subject of very different opinions by different obstetric authors Chailly says that authors have attempted to show that these discharges are due to the accumulation of fluid between chorion and amnion, to rupture of lymphatic vessels, to transudation through amniotic membranes, to rupture of the membranes at some remote point from the orifice of the uterus, and finally, to dropsy of the womb

Lusk says the pathological processes involved in the disease are vascularity, hyperæmia and hypertrophy of the interstitial connective tissue, and of the glandular elements of the decidua

Barnes, in the "System of Obstetric Medicine and Surgery," 1885, says in regard to these discharges, without entering into a critical discussion of the several theories, that it seems to be well established that there are five sources from which this fluid may come

1st A discharge from the cervical canal
2d The decidual origin
3d Transudation through amniotic membranes
4th Hydatidiform degeneration of the ovum
5th Cauliflower excrescences

The differential diagnosis must rest between the following similar discharges

From the discharge from hypertrophied cervical glands

Fluid collecting between chorion and amnion, occurring only once

Escape of fluid from amniotic cavity

I The fluid escaping from the hypertrophied glands must be small in quantity, and we would expect that it would continue for a considerable length of time There would be no diminution in the amount of liquor amnii and the child would be found floating in the usual amount of fluid

II If the fluid collected between any of the membranes, and adhesive inflammation surrounding it followed, a considerable amount of fluid might collect, and the discharges would be considerable at once, and might or might not be repeated In such a case there would be no evidence of escape of true amniotic fluid, although there might be a lessened size of the abdomen

III Where the liquor amnii escapes there would be a greater tendency to uterine contractions, a more perceptible diminution in the size of the uterine tumor, and a microscopical or chemical examination would certainly reveal some evidence of urine, as we know this exists in variable quantities in the liquor amnii

Transudation through the amniotic membrane, although recently noticed by Barnes, and mentioned by older authors, would give rise to the discharge of a very small amount of fluid

This could hardly be differentiated from a slight discharge taking place from the cervical glands Fluids discharged from hydatidiform degeneration of the chorion or from cauliflower excrescence, would be so associated with the diseases which cause them that the diagnosis would not be difficult

Prognosis —As far as my observation goes, the life of the woman is not jeopardized, but she suffers from the constant discharge and becomes anæmic The pain is sometimes severe, as I have before remarked, and the patient is full of gloomy forebodings, and anxious in regard to the final result

The fœtus is usually born prematurely, and, in many cases, only lives a short time

The treatment must necessarily be very simple—rest and anodynes being about all that can be suggested

DR H P MERRIMAN had one case of this kind about a year ago The woman had a sudden gush of water when she was not quite five months pregnant I thought it might presage labor, and told her to let me know of any symptoms of labor,—that I expected it would come on But she felt better after having had the gush of water She had, in the course of two or three weeks, another, and said she could tell when they were coming on, because she felt so full before they came When the second came I began to think that perhaps she was not going to have labor at the present time after all, that it probably was not a loss of the amniotic fluid, and I examined her and found the os not dilated I could feel, however, by carefully introducing my finger, that there was water still remaining there,—the amniotic bag remaining apparently intact I gave her opiates, thinking that labor might possibly be prevented She went along for nearly a month after that, before she finally miscarried She had three separate gushes of water at intervals of two or three weeks before her miscarriage finally came on The fœtus had perhaps a little over six months of intra uterine life at the time of its expulsion

It strikes me that we might learn by careful examination of the placenta and membranes after delivery, a great deal more than we have yet learned about this subject I cannot help thinking that there must be some defect in the fœtal envelopes to have a thing like this occur It could not have been a rupture of the amnion, but there may have been a separation between the amnion and the chorion, as I have seen in one other case in my own practice, in which the infant or fœtus enveloped in the amnion came away, leaving the chorion within the uterine cavity And we had a similar case presented to the Society a year ago, by Dr Sawyer The amnion had been separated from the chorion, and came away intact by an effusion of liquid between the chorion and amnion Now, if that takes place, why of course there may be a separation in part and then adhesion again after the occurrence of the rupture Any gush of this kind indicates, to me at least, some disturbance of the fœtal envelopes, either of the chorion or amnion, or a cystic degeneration of the placenta, and it strikes me that in every case of this kind the placenta and membranes ought to be carefully observed after the delivery, to see what pathological cause brought on the abortion

I would like to state in addition to my case, that the woman finally had her miscarriage quite suddenly I was not present, and another physician was called

The President said that he would like to ask a question as to whether there is any specific cause operative in the production of these cases? Whether syphilitic or gonorrhœal infection may have anything to do with it, and also whether inflammation of the mucous membrane of the uterus precedes these causes? Is it, in other words, an acute or chronic inflammation of the mucous membrane that causes it?

Dr Henry T Byford had nothing to add, except that Dr C R Parke, of Illinois, reported a case to him, in which the discharge of the liquor amnii took place, labor pains came on, and the umbilical cord became prolapsed He replaced the cord and gave ergot As labor did not progress, he finally gave morphia and quieted the pains In three months the woman was delivered of a living child, both did well

Dr H P Newman had seen a single case The discharge, however, was greater than in the cases related, and came on about six weeks previous to the abortion, the membranes were not examined

Dr W W Jaggard said that he had listened to the reading of Dr Earle's paper and the discussion with great interest He could not, however, agree with the author of the paper in considering the pathology of *hydrorrhœa uteri gravidi* as obscure and confused in all its details Carl Braun (*Zeitschr d Ges d Wiener Aerzte*, 1858, No 17, p 257) and C Hennig (*Der Katarrh der inneren weiblichen Geschlechtstheile*, Leipzig, 1860, p 48), had clearly and distinctly described the pathological anatomy of the condition Chronic decidual endometritis may terminate in the formation of new connective tissue, or may manifest itself by the production of a yellow, sero albuminous fluid, variable in quantity, which accumulates between *decidua vera* and *reflexa*, or when *vera* and *reflexa* are united, between decidua and chorion Carl Braun accordingly considers the condition to be a *serous endometritis* Hennig aptly terms it *catarrhal decidual endometritis* Catarrhal decidual endometritis must be distinguished from collections of fluid between the amnion and chorion, the so called amnio chorial water Bischoff has designated the unorganized, albuminous fluid uniting chorion and amnion as the *tunica media* The quantity of this fluid may increase abnormally, at the same time that its consistency is diminished McClintock describes a case, referred to by Spiegelberg, in which the amount of "amnio chorial water" was so great as to simulate hydramnios The "amnio-chorial water" may be discharged without the interruption of pregnancy, but then the discharge of fluid is not repeated, as in the intermittent discharges of *hydrorrhœa uteri gravidi* Labor always follows the rupture of the amniotic sac,—a fact which establishes the possibility of a differential diagnosis in the large majority of cases It is unusual for labor to be prematurely induced by the discharge of the "amnio-chorial water," or collections of catarrhal secretions between chorion and decidua

A condition strictly analogous to *hydrorrhœa uteri gravidi* is frequently observed in uterine fibroids The intermittent discharge of a yellowish sero albuminous fluid from the uterine cavity is a symptom of such frequent occurrence in this condition that attention is directed to it by most systematic writers

With reference to the etiology of *hydrorrhœa uteri gravidi*, there were several facts of practical import Any antecedent endometritis—gonorrhœal, syphilitic or of other origin—is an adequate etiological factor Hydræmia appears to favor the development of the condition The coincidence of hydræmia with catarrhal decidual endometritis would certainly indicate the exhibition of chalybeate tonics in the treatment of the latter affection

He fully agreed with Dr Merriman in attaching great importance to the critical examination of the fœtal envelopes in order to clear up a doubtful diagnosis

Dr Edward Warren Sawyer called attention to the fact that watery discharges from the uterine cavity frequently occurred during the *puerperium* He thought that the condition technically termed *hydrorrhœa gravidarum*, was due in all cases to the transudation of the amniotic fluid This was the opinion ably advocated by Charpentier

Dr W W Jaggard thought Dr Sawyer had not quoted Charpentier correctly Charpentier mentions Stapfer's recent monograph (*These de Concours*, 1880), in flattering terms, enumerates the various hypotheses proposed by a large number of observers, and says the German theory, already referred to, is the most probable

Dr Charles Warrington Earle had but very little to say in closing the discussion It seemed to him, however, that there was one thing, at least, that we should learn from our consideration of this subject this evening It seems to be impossible for any one to determine the exact source from which a considerable amount of fluid is occasionally discharged from the vagina of a pregnant woman We do not know whether this fluid comes from the amniotic cavity or external to it, therefore, we should not give ergot or commence the dilatation of the os uteri after a watery discharge, believing that labor must come on, because from the testimony we have received here to-night, and from other evidence, it does seem that even if the liquor amnii is prematurely evacuated in a few cases, pregnancy may go on to full term My attention has been called to the phenomenon mentioned by Dr Sawyer, and if I had not desired to make my paper as brief as possible, I should have spoken of the watery discharges which occasionally take place after labor I have never seen a case, but it is mentioned in the literature, and it is believed by those who have written upon the subject that the fluid in these cases comes from either the large lymphatic vessels, or perhaps from a continuation of the same disease which produced the discharge before Dr Sawyer is certainly not quite in accord with the majority of authorities when he says that the discharges of pregnancy always come from the cavity of the amnion

Dr Sawyer No, but the term "hydrorrhœa" should be reserved for that class of cases

Dr Earle This is not hydrorrhœa, as I understand it The term should be applied to a discharge of fluid from outside of the amniotic membrane, perhaps not from outside of the chorion, but certainly from outside of the amnion

(*To be concluded*)

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 10, 1886

The President, C H A Kleinschmidt, M D, in the Chair

T E McArdle, M D, Secretary

(*Concluded from page 273*)

Dr J Taber Johnson read a paper on

THE MECHANICAL TREATMENT OF THE VOMITING OF PREGNANCY

(See page 284)

Dr A Y P Garnett said that Dr Johnson had covered the ground so completely that there was not much left to be said It is evident from the paper that the weight of testimony is in favor of Copeman's method Now, what Dr Garnett desired to know, was why irritation of the os uteri should cause vomiting? How does this irritation act so as to produce vomiting? It seemed to him that the presence of the fœtus in the early months of pregnancy would have but little influence on the os And yet it is during this time that the vomiting usually occurs As the pregnancy progresses towards the later months and the os is involved, then the vomiting, as a rule, ceases of its own accord

Dr Johnson replied that softening of the neck of the uterus is one of the early signs of pregnancy In some cases, however, this softening does not occur The circular bands fail to dilate, and reflex sympathetic disturbance of the stomach is the result

Dr Garnett contended that in the second week of pregnancy, when the vomiting usually sets in, there is no necessity for a softened os Moreover, a somewhat similar disturbance of the stomach often occurs at the menstrual epoch, when the patient has a non gravid uterus He was much more inclined to adopt Grailey Hewitt's theory, and consider flexions of the uterus as a frequent cause of the vomiting of pregnancy In reply to Dr Smith, Dr Garnett said it would not militate against this theory to advance the fact that nearly every pregnant woman suffers more or less from vomiting, for may not nearly every woman have some displacement of the uterus?

Dr A F A King said he believed Copeman's method was beneficial because it relieved uterine congestion So, too, with the correction of displacements In a word, congestion of the uterus, no matter how produced, must be relieved The mode in which Copeman's method stopped the vomiting of pregnancy was by producing contraction of the womb, by which the organ was relieved of its congestion

Dr S C Busey asked Dr Johnson if the genu pectoral position is a remedy for all displacements?

Dr Johnson replied that Dr Campbell contended it is equally beneficial in all cases

Dr Busey then said that he had asked the question because he could not comprehend how the correction could be maintained in a case of anteversion after the patient had assumed the erect posture

Dr Johnson said of course some form of pessary must be applied

Dr Busey said there is more of hysteria in the vomiting of pregnancy than most medical men will admit, but less than Hewitt claims He thought the correction of displacements would relieve some forms of gravid nausea, but fail in others Copeman's method has carried many women to full term, but it does not always succeed Such a means, however, must always be considered a *dernier ressort* Perhaps Dr Johnson does Grailey Hewitt an injustice That gentleman did not state that the vomiting of pregnancy was due solely to displacements of the uterus, but to that cause and to contractions at the internal os

Dr King said the genu pectoral position would cure the displacement and thus relieve congestion It was the latter factor, in his opinion, which caused the vomiting, and Copeman's method would relieve

sanctum, as well as the sacred homes of its corps of editors, unfortified against the menacing disaster—disparaging an attempt to battle the hitherto unconquered enemy, is an incongruity of action which, to professional men living beyond the borders of yellow fever invasion, can be looked upon only as being prompted by motives which are not apparent to the public Its tender regard for the $30,000 of the funds of the United States as against the happiness, comfort and lives of the people of a vast area of this republic is too unreasonable even to credit, and must be received as a flimsy screen to conceal the animus of its opposition The assertion that the investigations of Freire and Carmona are without scientific value seems to my mind little less than a distortion of facts, and unwarranted without further investigation Freire's investigations, as recorded in his voluminous illustrated report to the Brazilian government, show an amount of scientific work that places him among the first biologists of the day, and, if his conclusions are correct, as there now appears to be no reason to doubt, crowns him as the greatest living benefactor of the human race The statistical record of his vaccinations just published (1886), together with the deaths from yellow fever in Rio de Janeiro from January to August last, presents an array of facts that cannot be controverted by any method of argument

"For a publication, whatever its name or kind, pretending to wear the dress of mediocrity even, to attempt to defeat the investigations by the general government into the means and methods of saving life and of maintaining unbroken, so long as natural law has ordained, the unit of our country's strength and prosperity—the family circle—is unless some superior plan is offered with an assurance of its adoption and execution, lamentable beyond expression when viewed from the standpoint of human love or moral duty We, at the North, with our homes safe from this one monster of death, with a patriotic regard for the welfare of every community in this great sisterhood of States, and with hearts tender to the wails of distress which we have too often heard from the sorrowing homes of the sunny South, that have been stricken with this terrible disease, join with you, your associates, and the American Public Health Association, in urging the passage of the bill now before Congress This measure is supported upon the broad principle of humanity and loyalty to public interests, by men in old New England, but to see opposition to it springing up from men living in a district that has more than once been decimated by the frightful pestilence, is an anomaly which we must believe incompatible with common sense"

ASTLEY COOPER PRIZE —It is announced that the next triennial prize of £300, under the will of the late Sir Astley P Cooper, Bart, will be awarded, early in 1889, to the author of the best essay or trea-
ı "The Origin, Anatomy, Results, and Treat-
of Tubercular Diseases of Bones and Joints"
essays shall contain original experiments and
ervations which shall not have been previously

DR W W JAGGARD thought Dr Sawyer had not quoted Charpentier correctly Charpentier mentions Stapfer's recent monograph (*These de Concours*, 1880), in flattering terms, enumerates the various hypotheses proposed by a large number of observers, and says the German theory, already referred to, is the most probable

DR CHARLES WARRINGTON EARLE had but very little to say in closing the discussion It seemed to him, however, that there was one thing, at least, that we should learn from our consideration of this subject this evening It seems to be impossible for any one to determine the exact source from which a considerable amount of fluid is occasionally discharged from the vagina of a pregnant woman We do not know whether this fluid comes from the amniotic cavity or external to it, therefore, we should not give ergot or commence the dilatation of the os uteri after a watery discharge, believing that labor must come on, because from the testimony we have received here to night, and from other evidence, it does seem that even if the liquor amnii is prematurely evacuated in a few cases, pregnancy may go on to full term My attention has been called to the phenomenon mentioned by Dr Sawyer, and if I had not desired to make my paper as brief as possible, I should have spoken of the watery discharges which occasionally take place after labor I have never seen a case, but it is mentioned in the literature, and it is believed by those who have written upon the subject that the fluid in these cases comes from either the large lymphatic vessels, or perhaps from a continuation of the same disease which produced the discharge before Dr Sawyer is certainly not quite in accord with the majority of authorities when he says that the discharges of pregnancy always come from the cavity of the amnion

DR SAWYER No, but the term "hydrorrhœa" should be reserved for that class of cases

DR EARLE This is not hydrorrhœa, as I understand it The term should be applied to a discharge of fluid from outside of the amniotic membrane, perhaps not from outside of the chorion, but certainly from outside of the amnion

(*To be concluded*)

MEDICAL SOCIETY OF THE DISTRICT OF COLUMBIA

Stated Meeting, February 10, 1886

THE PRESIDENT, C H A KLEINSCHMIDT, M D, IN THE CHAIR

T E MCARDLE, M D, SECRETARY

(*Concluded from page 273*)

DR J TABER JOHNSON read a paper on

THE MECHANICAL TREATMENT OF THE VOMITING OF PREGNANCY

(See page 284)

DR A Y P GARNETT said that Dr Johnson had covered the ground so completely that there was not much left to be said It is evident from the paper that the weight of testimony is in favor of Copeman's method Now, what Dr Garnett desired to know, was why irritation of the os uteri should cause vomiting? How does this irritation act so as to produce vomiting? It seemed to him that the presence of the fœtus in the early months of pregnancy would have but little influence on the os And yet it is during this time that the vomiting usually occurs As the pregnancy progresses towards the later months and the os is involved, then the vomiting, as a rule, ceases of its own accord

DR JOHNSON replied that softening of the neck of the uterus is one of the early signs of pregnancy In some cases, however, this softening does not occur The circular bands fail to dilate, and reflex sympathetic disturbance of the stomach is the result

DR GARNETT contended that in the second week of pregnancy, when the vomiting usually sets in, there is no necessity for a softened os Moreover, a somewhat similar disturbance of the stomach often occurs at the menstrual epoch, when the patient has a non gravid uterus He was much more inclined to adopt Grailey Hewitt's theory, and consider flexions of the uterus as a frequent cause of the vomiting of pregnancy In reply to Dr Smith, Dr Garnett said it would not militate against this theory to advance the fact that nearly every pregnant woman suffers more or less from vomiting, for may not nearly every woman have some displacement of the uterus?

DR A F A KING said he believed Copeman's method was beneficial because it relieved uterine congestion So, too, with the correction of displacements In a word, congestion of the uterus, no matter how produced, must be relieved The mode in which Copeman's method stopped the vomiting of pregnancy was by producing contraction of the womb, by which the organ was relieved of its congestion

DR S C BUSEY asked Dr Johnson if the genupectoral position is a remedy for all displacements?

DR JOHNSON replied that Dr Campbell contended it is equally beneficial in all cases

DR BUSEY then said that he had asked the question because he could not comprehend how the correction could be maintained in a case of anteversion after the patient had assumed the erect posture

DR JOHNSON said of course some form of pessary must be applied

DR BUSEY said there is more of hysteria in the vomiting of pregnancy than most medical men will admit, but less than Hewitt claims He thought the correction of displacements would relieve some forms of gravid nausea, but fail in others Copeman's method has carried many women to full term, but it does not always succeed Such a means, however, must always be considered a *dernier ressort* Perhaps Dr Johnson does Grailey Hewitt an injustice That gentleman did not state that the vomiting of pregnancy was due solely to displacements of the uterus, but to that cause and to contractions at the internal os

DR KING said the genu pectoral position would cure the displacement and thus relieve congestion It was the latter factor, in his opinion, which caused the vomiting, and Copeman's method would relieve it when it was due to a contracted os. Dr. Johnson had done too much at one sitting. If he had dilated the cervix a little the first time, and several hours afterwards repeated the attempt, he would not have run so great a risk of producing an abortion.

Dr. Busey said that Copeman had accidentally discovered this method of relieving the vomiting of pregnancy. He intended to produce an abortion in a certain case by dilating the cervix. The patient did not abort, but the vomiting was relieved. Dr. King may not be correct in his opinion that Dr. Johnson would not have produced an abortion if he had not been so precipitate. Such a result will happen sometimes despite every precaution. The dilatation should be effective, and the physician is not responsible for the abortion. It is true that it is not necessary for the dilatation to be carried to the internal os at the first sitting. A second trial may be made some hours later.

Dr. King contended that Dr. Copeman had not dilated sufficiently to produce an abortion. Another point to be taken into consideration is the predisposition of some women to abort on the slightest provocation.

Dr. Johnson, in reply to a question by Dr. Smith, said that his patient had a prolapsed and anteverted uterus. He corrected the displacements, but with no effect on the vomiting.

Dr. Smith said it looked like a *deliberate* attempt to produce an *accidental* abortion. Dr. Johnson pulls down the uterus with a tenaculum, and after using a dilator, places his finger in the cervix and makes a "boring and forcing movement." Dr. Smith knew of no better method for producing an abortion. In Dr. Smith's experience displacements of the uterus did not seem to be a potent factor in the production of the vomiting of pregnancy. At least, the vomiting was not increased in ratio of greatest displacement. He, therefore, had no faith in Hewitt's views. He agreed with Dr. Garnett that the cervix has nothing to do with the body of the uterus until towards the end of the pregnancy.

Dr. Bromwell read a quotation from Barnes in reference to the advisability of trying Copeman's method.

Dr. J. B. Hamilton said it occurred to him that even the correction of a displacement frequently produces an abortion, especially when a pessary is used to retain the uterus—so that the criticism against Copeman's operation was scarcely a fair one.

Dr. Busey said the abortion might occur even if the pessary were not applied.

Dr. Johnson, in closing the discussion, said he could hardly believe that Dr. Smith was in earnest. Copeman's method is an acknowledged means of relief, and has received the sanction of obstetric authorities. He was inclined to agree with Dr. King that if he had dilated more slowly, and had not finished for a day or two, the result might have been different. Dr. Smith's experience with displacements was too limited to be put in opposition to the numerous recorded cases of vomiting being relieved by the correction of displacements.

FOREIGN CORRESPONDENCE

LETTER FROM LONDON

(FROM OUR OWN CORRESPONDENT.)

Bacterial Therapeutics—Mortality among Medical Men—Cerebral Abscess after Empyema—Portrait of William Harvey.

The theory of the survival of the fittest, and consequently that in the struggle for existence the weakest must go to the wall, has led Dr. Cantani to apply these principles in the case of one particular germ—the bacillus tuberculosus, or that which causes consumption—to be opposed by another species of germ. His idea is that of encouraging the natural warfare of the germs already noted. The battle field here is the human lung. The combatants are the bacillus just mentioned and a certain other germ known as the bacterium termo. Both combatants are well known in the field of microscopic inquiry, and the hoped for result of the battle is the rout of bacillus by bacterium, in other words, the clearance from the lung of the former and disease producing germ by one which is not disease-producing, and which in the struggle for existence will kill off its opponent. The bacterium termo is found in the ordinary processes of decay. Making sure in the first instance of his ground, Dr. Cantani, by experiments upon animals, proved that the termo could not produce disease. Next came the actual application of the remedy and the opposing of the harmless bacterium to the noxious bacillus in the lung. A consumptive patient was selected for this interesting experiment. That the case was one of true phthisis was proved in the accustomed fashion. Animals inoculated with the matter brought up from the patient's lungs developed consumption, and died of the disease in a few weeks' time. The bacterium cure is now prepared. This germ has been cultivated in a suitable medium—liquefied gelatine and meat broth. The patient is made to inhale this culture of the bacterium daily. The results are, to say the least, curious. The cough and expectoration diminish. The bacilli grow fewer and fewer, until they are no longer to be detected in the expectoration. In less than a month after commencing the inhalation the disease germs can no longer be seen, and, most satisfactory result of all, the matter from the lungs no longer produces consumption in animals inoculated therewith. In the struggle for existence the, to man, harmless germ has replaced and killed off the germ of the fell disorder.

Cantani's method has been followed out by other physicians. A Dr. Salama, of Pisa, has experimented in similar fashion. On July 17 last, the inhalations of the bacterium were commenced in the case of a consumptive patient in whom all the symptoms of the disease were unmistakably present. On August 2 the bacillus had disappeared, and the patient, as in the other case, gained strength and flesh rapidly. No one can for a moment pretend to believe that at last a sure remedy has been found for consumption, nor is this Dr. Cantani's contention. His aim is to illustrate and to apply practically a principle in biological science to the cure of disease It may be that other harmless germs will be found in the already long lists of microscopists, which will serve the purpose of soldiers fighting for health against disease even better than the bacterium termo itself It is something gained in the fight against disease to know that there is a possibility of opposing successfully one germ against another The future of medicine may include possibilities of the kind such as may throw vaccination and its concomitant practices completely into the shade At the very least it is noteworthy to observe how, from the very domain of science, which has flooded us with the knowledge of disease germs and their terrible power over human life, there comes a hopeful echo of ways and means for counterbalancing the malign influences these microscopic particles exercise on our physical well-being

The Statistical Department of the Registrar-General's Office has published some interesting facts with regard to the mortality in the medical profession According to Dr Ogle, the Superintendent, there were in 1881 no less than 15,091 duly registered medical practitioners, and it appears that the death rate is not only high, but it is also on the increase In the years 1880, 1881 and 1882 the mortality was higher than that seen in other professions It was also above the death rate exhibited by doctors for two decades or so before, it being 25 53 per thousand The worries of the law, it would appear, do not militate against forensic well being, the lawyers died during the same period at the rate of 20 23 per 1,000, and the clergy show a death-rate of only 15 93 Again, when the medical mortality is compared with the death-rate of teachers, with that of commercial travelers, or even with that of the miner and his coal dust lungs, these fairly unhealthy and very unsanitary occupations are found to present favorable comparison with the doctor's chances of old age The innkeeper, butcher, brewer, quarryman, cutler, and workers in certain other trades are behind doctors in the matter of mortality Coming to more intimate details, Dr Ogle says that some 388 deaths occur each year among the doctors of England and Wales Adding in the Scottish and Irish mortality, it is probable one may set down the number 770 as representing very nearly the total deaths of medical men per annum The causes of death per million of medical men and per million of other men, the death-rate from scarlet fever is as 59 to 16, from typhus as 79 to 38, from diphtheria as 59 to 14, from typhoid fever as 311 to 238, from alcoholism even, as 178 to 130, from suicide as 363 to 238 In the matter of suicide, self-destruction by poison is the preferential method of the profession Liver diseases kill off a moiety of the profession, and a great authority has explained this fact by a reference to the irregular dietetic habits which the business habits of a doctor induce In the matter of small pox the profession comes out triumphantly The annual death rate from small-pox among all males above 20 years of age is 73 per million Among medical men it is only 13 per million These researches show indisputably that the war against disease is one attended with risks of no mean kind, and that those who fight the battle are exposed to chances of death above those incurred by nearly all their fellows

At the last meeting of the Medical Society of London an interesting discussion took place, upon the occurrence of cerebral abscess after attacks of empyema A case was mentioned of a patient, a governess, aged 20, who had suffered from empyema which had opened spontaneously Later, however, a sinus remained, and portions of the fourth and fifth rib were excised and the pleural cavity washed out In eight days this was followed by attacks of an epileptiform character, vomiting, coma and death At the necropsy an abscess three inches long was found in the anterior lobe of the right hemisphere of the cerebrum

An interesting portrait of William Harvey is being etched by M Walther for Messrs Colnaghi & Co, of Pall Mall East The original belongs to the Royal College of Physicians G O M

ASSOCIATION ITEMS

AMERICAN MEDICAL ASSOCIATION

The Thirty-seventh Annual Session will be held in St Louis, Mo, on Tuesday, Wednesday, Thursday and Friday, May 4, 5, 6 and 7, commencing on Tuesday at 11 A M

The delegates shall receive their appointment from permanently organized State Medical Societies and such County and District Medical Societies *as are recognized by representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States

Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number *Provided*, however, that the number of delegates for any particular State, territory, county, city or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the Secretaries *are, by special resolution*, requested to send to him, annually, a corrected list of the membership of their respective Societies

SECTIONS

"The Chairman of the several Sections shall prepare and read, in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections "—*By Laws*, Article 11, Sec 4

Ophthalmology, Otology, Laryngology —Dr Eugene Smith, Detroit, Mich , *Chairman*, Dr J F Fulton, St Paul, Minn , *Secretary*

Diseases of Children —Dr W D Haggard, Nashville, Tenn , *Chairman*, Dr W B Lawrence, Batesville, Ark , *Secretary*

Oral and Dental Surgery —Dr John S Marshall, Chicago, Ill , *Chairman*, Dr A E Baldwin, Chicago, Ill , *Secretary*

A member desiring to read a paper before a Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of Arrangements, at least one month before the meeting —*By-Laws*

Committee of Arrangements —Dr Le Grand Atwood, St Louis, Missouri, *Chairman*

AMENDMENTS TO BY-LAWS

By Dr Foster Pratt, Mich —Each Section shall nominate its Chairman and Secretary—all other nominations to be made, as now, by the nominating Committee

By Dr I N Quimby, N J—Create a new Section, to be known as the Section on Medical Jurisprudence

Wm B Atkinson, M D ,
Permanent Secretary
1400 Pine St , S W cor Broad, Philadelphia

MISCELLANEOUS.

The Yellow Fever Commission —The unfriendly attitude of a contemporary towards the proposed "Yellow Fever Commission" has called out an able letter from Dr Irving A Watson, of New Hampshire, to Louisiana's distinguished sanitarian, Dr Joseph Holt The following extracts are taken from his letter, which is published in the *Sanitary News*, of March 6

"It was to be expected that hostile influences would spring up where the personal interests of a few were jeopardized, and from some who place selfish motives above moral principles, jealousies before humanitarian philanthropy, and to whom revenge is sweeter than the disenthrallment of their own communities from the terrible slaughter of a relentless and uncompromising pestilence It would not have caused surprise to have found some crabbed medical journal in a state of chronic hostility to advancement in science, opposing the measure, because of its inherent inability to do otherwise, but, for a so called reputable publication, like the New Orleans *Medical and Surgical Journal*, to lead the attack in what appears to be an unchivalric and unprofessional manner, a journal having its own sanctum, as well as the sacred homes of its corps of editors, unfortified against the menacing disaster—disparaging an attempt to battle the hitherto unconquered enemy, is an incongruity of action which, to professional men living beyond the borders of yellow fever invasion, can be looked upon only as being prompted by motives which are not apparent to the public Its tender regard for the $30,000 of the funds of the United States as against the happiness, comfort and lives of the people of a vast area of this republic is too unreasonable even to credit, and must be received as a flimsy screen to conceal the animus of its opposition The assertion that the investigations of Freire and Carmona are without scientific value seems to my mind little less than a distortion of facts, and unwarranted without further investigation Freire's investigations, as recorded in his voluminous illustrated report to the Brazilian government, show an amount of scientific work that places him among the first biologists of the day, and, if his conclusions are correct, as there now appears to be no reason to doubt, crowns him as the greatest living benefactor of the human race The statistical record of his vaccinations just published (1886), together with the deaths from yellow fever in Rio de Janeiro from January to August last, presents an array of facts that cannot be controverted by any method of argument

"For a publication, whatever its name or kind, pretending to wear the dress of mediocrity even, to attempt to defeat the investigations by the general government into the means and methods of saving life and of maintaining unbroken, so long as natural law has ordained, the unit of our country's strength and prosperity—the family circle—is unless some superior plan is offered with an assurance of its adoption and execution, lamentable beyond expression when viewed from the standpoint of human love or moral duty We, at the North, with our homes safe from this one monster of death, with a patriotic regard for the welfare of every community in this great sisterhood of States, and with hearts tender to the wails of distress which we have too often heard from the sorrowing homes of the sunny South, that have been stricken with this terrible disease, join with you, your associates, and the American Public Health Association, in urging the passage of the bill now before Congress This measure is supported upon the broad principle of humanity and loyalty to public interests, by men in old New England, but to see opposition to it springing up from men living in a district that has more than once been decimated by the frightful pestilence, is an anomaly which we must believe incompatible with common sense"

Astley Cooper Prize —It is announced that the next triennial prize of £300, under the will of the late Sir Astley P Cooper, Bart , will be awarded, early in 1889, to the author of the best essay or treatise on "The Origin, Anatomy, Results, and Treatment of Tubercular Diseases of Bones and Joints" The essays shall contain original experiments and observations which shall not have been previously published, and that each essay shall (as far as the subject shall admit of) be illustrated by preparations and drawings, which shall be added to the Museum of Guy's Hospital, and shall, together with the work itself, become henceforth the property of that institution This prize is open for competition to the whole world, though the essay may not be the joint production of two or more authors Essays, either written in the English language, or, if in a foreign language, accompanied by an English translation, must be sent to Guy's Hospital on or before January 1st, 1889, addressed to the physicians and surgeons of Guy's Hospital Each essay or treatise must be distinguished by a motto, and accompanied by a sealed envelope containing the name and address of the writer None of the envelopes will be opened except that which accompanies the successful treatise The successful essays or treatises, with the illustrative preparations or drawings, will remain at the Museum of Guy's Hospital until claimed by the respective writers or their agents A printed form, giving particulars regarding the conditions to be complied with, may be had on application to the Dean, Guy's Hospital, Southwark, S E

THE DAKOTA MEDICAL BRIEF, is the title of another new journal, the first number to appear on the 1st of April next, at Mitchell, Dakota It is to be published monthly, and edited by F Andros, A M , M D , and H S Sevey, M D

DR LOUIS BALCH, of Albany, has been appointed Secretary of the New York State Board of Health

---

THE CAUSE OF IT —An English contemporary says, in advocating the muzzling of dogs as a preventive of hydrophobia "A muzzle at any rate, cannot be more uncomfortable than high heeled boots, tight stays, or chimney-pot hats " If dogs in London are afflicted with these things there is no great wonder that they go mad

---

PURCHASED AMERICAN DEGREES IN GERMANY — It is said that proceedings are soon to be instituted in Germany against persons styling themselves "Doctor" on the strength of diplomas purchased from America *in absentiâ* There are said to be 3400 of these "doctors" in Berlin alone, either of medicine, philosophy, or law

---

THE ILLINOIS STATE BOARD OF HEALTH has just issued a revised "Register of Physicians and Midwifes in Illinois," and recently its seventh Annual Report, for the year 1884 The report on medical education show an increasing uniformity in the methods and practices of medical colleges

---

A READY MEANS OF PRESERVING THE FLUIDITY OF BLOOD —A student in Professor Stricker's laboratory, Herr Ernest Freund, has, it seems, suggested a most simple and convenient method of preserving blood in the fluid state His plan consists in coating the interior of a glass vessel with pure oil Into this receptacle blood freshly drawn is poured, and a layer of oil is then run over the surface exposed to the air In this way we are assured, fresh blood may be kept from coagulating for days if necessary It is difficult to see how so simple an experiment, if once satisfactorily demonstrated, should afterwards be discredited by repetition We may therefore hope that this apparently trivial application of a physical law will be a real gain to practice as well as research In particular it should obviously facilitate the operation of transfusion, though it will not entirely replace that still more ready means of treatment, salt solution. It need hardly be said that this mode of preventing coagulation is new rather in its easy and general application than as illustrating a principle for the first time discovered Professor Ludwig made use of the same idea in estimating the velocity of the blood-current —*The Lancet*, Feb 20, 1886

THE MASTER PLUMBERS OF BALTIMORE have prepared a bill designed to prevent incompetent persons from carrying on the plumbing business in Maryland. It provides that the Governor shall appoint biennially five persons, to constitute the "State Board of Commissioners of Practical Plumbing," three of whom are to be skilled plumbers from Baltimore, one the Commissioner of Health of Baltimore, and the fifth to be a member of the State Board of Health

---

OHIO SANITARY ASSOCIATION —At the recent meeting of this active Association, held in Columbus, the following were elected officers for the ensuing year President, Dr S H Herrick, of Cleveland, Vice Presidents, Prof E T Nelson, Ph D , of Delaware, W H Phillips, M D , of Kenton, C P Landon, M D ,, of Westerville, Secretary, R Harvey Reed, M D of Mansfield, Treasurer, Prof John Simpson, Ph D , of Mansfield

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT U S ARMY FROM FEBRUARY , 1886 TO MARCH 6 1886

Major J W Williams, Surgeon, ordered for duty as post surgeon, Vancouver Barracks, Washington Ter

Capt C E Munn, Asst Surgeon, ordered for duty as post surgeon, Ft Cœur d'Alene, I T

Capt M W Wood, Asst Surgeon, ordered for duty as post surgeon, Ft Walla Walla, Washington Ter (S O [illegible], Dept Col , Feb 20, 1886)

Major Wm S Tremaine, Surgeon, leave of absence extended six months, on surgeon's certificate of disability (S O [illegible], A G O , March 2, 1886)

Major Henry McElderry, Surgeon U S Army, leave of absence extended one month (S O 49, A G O March 1, 1886.)

Capt Wm G Spencer, Asst Surgeon, ordered for duty at Ft. Yates, D T (S O 17 Dept Dak , Feb 23, 1886.)

To be Asst Surgeons with the rank of captain, after five years' service, in accordance with the act of June 23, 1884

Asst Surgeon Wm H Arthur, Feb 18, 1886

Asst Surgeon Geo E Bushnell, Feb 18, 1886

Asst Surgeon Henry P Birmingham, Feb 18, 1886

Asst Surgeon Marlborough C Wyeth, Feb 18, 1886 (Circular A G O , March 1, 1886)

TUBERCULOSIS PULMONUM, ACUTE AND CHRONIC —ITS NATURE AND TREATMENT

BY A S v MANSFELDE, M D,
OF ASHLAND NEB
PERMANENT SECRETARY, NEBRASKA STATE MEDICAL SOCIETY PRESIDENT OF THE RAILROAD SURGEONS' SOCIETY OF NEBRASKA ETC

I *The name* This was chosen because the word phthisis, hitherto used for chronic tuberculosis, in the mind of the clinician, comprises conditions with which our present inquiry has no part, and again, the word tuberculosis, as used by pathologists, does not fully cover the disease processes of which we shall speak Phthisis of the clinician may include all the destructive processes taking place in the lung, and except post mortem examination clear up the error, many diseases, such as multiple embolism of whatever nature, followed by necrosis of smaller or larger areas of lung tissue, some of them, by their extent, deserving the name of gangrene, are classed with phthisis

The pathologist, on the contrary, is inclined to exclude all processes from the clinical history of tuberculosis which are not accompanied by tubercles, be they gray or yellow, situated *in* the tissue or in the bronchial termini, though of late some have included all caseous deposits in the list of tuberculous conditions That both parties are incorrect in their exclusions and admissions will be a part of my work to prove in this paper For the purposes of this paper the term *tuberculosis* is meant to cover the manifold changes, acute and chronic, occurring in the body, in the presence or by the aid of a microscopic parasite, the *bacillus Kochii vel b tuberculosis* It is also claimed that a peculiar conformity of the lymphatics facilitates the occurrence of tuberculosis, that the seed, the bacillus, requires a porous soil for its entrance into the economy, that it must remain undisturbed during its germination, that it must find in the soil a proper and sufficient amount of food for its growth and propagation, that the disease is always caused by infection, that it is never inherited, and finally, that it is often curable It would be inexcusable repetition to give a history of the diseases and conditions which, from the time of Hippocrates, have been regarded as necessary factors of tuberculosis, suffice it to say that, however contradictory observations and deductions have been, all of them were aimed at the solution of this mightiest of medical problems, the stamping out of this terror of human kind—tuberculosis To facilitate comprehension, a description of the parts involved in the disease seems unavoidable The forty two ounces of lung tissue are composed of bronchial tubes ramifying in a dichotomous manner in every direction, until their terminal branches, the bronchioles, have diminished to a diameter of from 0 3 to 0 2 mm These tubes, from their origin, the trachea, to the lobulettes, or respiratory cavities, are composed of four layers, the external fibrous, a muscular, an internal fibrous, and a mucous membrane, with its ciliated cylinder epithelium Accompanying these tubes we have the pulmonary arteries, the bronchial arteries, pulmonary veins, bronchial veins, nerves and lymphatics, all surrounded by the *adventitia*, which consists of loosely interwoven connective tissue, traversed everywhere by large lymphatics, which have from their situation received the name of perivascular lymphatics and peribronchial lymphatics, respectively The bronchi are kept, for the greater part of their course, pervious by cartilaginous plates, which are contained in the external fibrous layer, here clusters of fat cells and mucous glands also abound The latter terminate by a straight duct, with trumpet shaped mouth upon the free surface Approaching the respiratory cavities the glands and cartilages disappear entirely, and the external fibrous layer in which they are imbedded, though constituting one half of the calibre of the larger tubes, diminishes to the size of a delicate membrane Upon this the muscular coat, consisting of delicate bands of smooth muscle cells, is placed, and upon that the internal fibrous layer, particularly noted for its elastic bands and fibres, which continue into the parenchyma of the lung The parenchyma proper consists of delicate connective tissue sheaths, which constitute the framework of the respiratory cavities, of connective tissue rich in elastic fibres, which tissue forms the septa of the contiguous alveoli, as well as the boundary tissue between systems of alveoli, called lobulettes, and their multiples, lobules

Between the septa and in the connective basis substance, close to the respiratory cavities, bloodvessels and capillaries, lymphatics and lymph spaces abound The alveoli or air vesicles are small shallow cavities, lined by a stunted epithelium of the cylindrical variety, assuming the type of the pavement epithelium, barely recognizable in the adult, yet easily observable in the new-born child The hyaline membrane composing these cavities carries upon its con-published, and that each essay shall (as far as the subject shall admit of) be illustrated by preparations and drawings, which shall be added to the Museum of Guy's Hospital, and shall, together with the work itself, become henceforth the property of that institution This prize is open for competition to the whole world, though the essay may not be the joint production of two or more authors Essays, either written in the English language, or, if in a foreign language, accompanied by an English translation, must be sent to Guy's Hospital on or before January 1st, 1889, addressed to the physicians and surgeons of Guy's Hospital Each essay or treatise must be distinguished by a motto, and accompanied by a sealed envelope containing the name and address of the writer None of the envelopes will be opened except that which accompanies the successful treatise The successful essays or treatises, with the illustrative preparations or drawings, will remain at the Museum of Guy's Hospital until claimed by the respective writers or their agents A printed form, giving particulars regarding the conditions to be complied with, may be had on application to the Dean, Guy's Hospital, Southwark, S E

TUBERCULOSIS PULMONUM, ACUTE AND CHRONIC —ITS NATURE AND TREATMENT

BY A S v MANSFELDE, M D,
OF ASHLAND NEB
PERMANENT SECRETARY, NEBRASKA STATE MEDICAL SOCIETY PRESIDENT OF THE RAILROAD SURGEONS SOCIETY OF NEBRASKA ETC

I *The name* This was chosen because the word phthisis, hitherto used for chronic tuberculosis, in the mind of the clinician, comprises conditions with which our present inquiry has no part, and again, the word tuberculosis, as used by pathologists, does not fully cover the disease processes of which we shall speak Phthisis of the clinician may include all the destructive processes taking place in the lung, and except post-mortem examination clear up the error, many diseases, such as multiple embolism of whatever nature, followed by necrosis of smaller or larger areas of lung tissue, some of them, by their extent, deserving the name of gangrene, are classed with phthisis

The pathologist, on the contrary, is inclined to exclude all processes from the clinical history of tuberculosis which are not accompanied by tubercles, be they gray or yellow, situated *in* the tissue or in the bronchial termini, though of late some have included all caseous deposits in the list of tuberculous conditions That both parties are incorrect in their exclusions and admissions will be a part of my work to prove in this paper For the purposes of this paper the term *tuberculosis* is meant to cover the manifold changes, acute and chronic, occurring in the body, in the presence or by the aid of a microscopic parasite, the *bacillus Kochii vel b tuberculosis* It is also claimed that a peculiar conformity of the lymphatics facilitates the occurrence of tuberculosis, that the seed, the bacillus, requires a porous soil for its entrance into the economy, that it must remain undisturbed during its germination, that it must find in the soil a proper and sufficient amount of food for its growth and propagation, that the disease is always caused by infection, that it is never inherited, and finally, that it is often curable It would be inexcusable repetition to give a history of the diseases and conditions which, from the time of Hippocrates, have been regarded as necessary factors of tuberculosis, suffice it to say that, however contradictory observations and deductions have been, all of them were aimed at the solution of this mightiest of medical problems, the stamping out of this terror of human kind—tuberculosis To facilitate comprehension, a description of the parts involved in the disease seems unavoidable The forty two ounces of lung tissue are composed of bronchial tubes ramifying in a dichotomous manner in every direction, until their terminal branches, the bronchioles, have diminished to a diameter of from 0 3 to 0 2 mm These tubes, from their origin, the trachea, to the lobulettes, or respiratory cavities, are composed of four layers, the external fibrous, a muscular, an internal fibrous, and a mucous membrane, with its ciliated cylinder epithelium Accompanying these tubes we have the pulmonary arteries, the bronchial arteries, pulmonary veins, bronchial veins, nerves and lymphatics, all surrounded by the *adventitia*, which consists of loosely interwoven connective tissue, traversed everywhere by large lymphatics, which have from their situation received the name of perivascular lymphatics and peribronchial lymphatics, respectively The bronchi are kept, for the greater part of their course, pervious by cartilaginous plates, which are contained in the external fibrous layer, here clusters of fat cells and mucous glands also abound The latter terminate by a straight duct, with trumpet shaped mouth upon the free surface Approaching the respiratory cavities the glands and cartilages disappear entirely, and the external fibrous layer in which they are imbedded, though constituting one half of the calibre of the larger tubes, diminishes to the size of a delicate membrane Upon this the muscular coat, consisting of delicate bands of smooth muscle cells, is placed, and upon that the internal fibrous layer, particularly noted for its elastic bands and fibres, which continue into the parenchyma of the lung The parenchyma proper consists of delicate connective tissue sheaths, which constitute the framework of the respiratory cavities, of connective tissue rich in elastic fibres, which tissue forms the septa of the contiguous alveoli, as well as the boundary tissue between systems of alveoli, called lobulettes, and their multiples, lobules

Between the septa and in the connective basis substance, close to the respiratory cavities, bloodvessels and capillaries, lymphatics and lymph spaces abound The alveoli or air vesicles are small shallow cavities, lined by a stunted epithelium of the cylindrical variety, assuming the type of the pavement epithelium, barely recognizable in the adult, yet easily observable in the new born child The hyaline membrane composing these cavities carries upon its convex surface the tortuous capillaries which intertwine in the septa of contiguous alveoli, and so closely do these minute blood-vessels embrace the alveoli, that their delicate arms sink by more than half into the cavity of the air vesicle. A number of alveoli grouped together form an infundibulum, several infundibula terminate in one common passage—still composed of air vesicles—the alveolar passage, three or four of which form a lobulette, or acinus of the lung, ten or fifteen of these comprise a lobule, and these again join to form the three lobes of the right, and two lobes of the left lung. The lymphatics, as everywhere in the body, so also in the lung, take their origin from surfaces covered by epithelium and endothelium in the following manner. As is known, both the epi and endothelial cells covering surfaces are not contiguous, but are separated by what is called cement substance, and this substance does not adhere intimately to the apposite cells, but sufficient space remains for the transmission of fine particles, of solid substances even, such as sulphindigate of soda, as has been so beautifully demonstrated as occurring in the kidney, *i. e.*, from the capillaries surrounding the uriniferous tubules to the lumen of the latter (Heidenhain demonstrating the excretion of solid substances by these channels).

It is very probable that this cell cement forms part of the bodies of connective tissue corpuscles, for it is in proximity to these elements of the fibrous connective tissue and their derivatives, the fibres, or bundles of fibres, that we find the first traces of lymphatics; these are lymph spaces, minute irregular channels, lined with the same delicate endothelial plates which we are accustomed to find in blood and lymph capillaries, and they, the lymph-spaces, occupy the intermediate ground between these two systems of vessels, the blood capillaries leading to them and the lymph capillaries from them. Now, when we remember that the alveoli or air vesicles have a diameter of 0·1 to 0·4 mm., and that the capillaries nearest them have a diameter of 0·0045 to 0·0113 mm., and presumably nearer the smaller limit, as the capillaries of the lung belong to the narrowest in the body, we will realize the smallness of the lymph spaces, which do not admit blood corpuscles under ordinary circumstances. The dimensions of these lymph spaces would be inconceivable were it not for the aid which the microscope vouchsafes, and yet it is here, and only here, where the battle for life and supremacy between the elements of the body on the one hand, and the bacilli upon the other, takes place.

The bacillus tuberculosis vel Kochii.—At the meeting of the Berlin Physiological Society on March 24, 1882, Dr. Robert Koch announced that he had found by a process of double staining (with methyl blue and vesuvin), a bacillus of the length of one third the diameter of a blood corpuscle (0·0026 mm.), with a breadth of one-sixth to one fifth of its own length (0·0004 to 0·0005 mm.). That this bacillus occurred in fresh tubercles and more sparingly in older ones, that he had cultivated them upon solid media (Nahrboden), composed of coagulated blood serum, that they grew very slowly, needing about two to four weeks for their life-cycle, and that they required a temperature between 86° and 105° Fahrenheit for their development, that he had grown several generations of these bacilli, and that members of each generation, introduced into the bodies of other animals, had given rise to tuberculosis, that, therefore, *this bacillus is the infective agent by which, or in the presence of which tuberculosis develops* (and not simply *tubercles*, as many writers seem to think, for tuberculosis is a pathological entity, tubercles simply an anatomical one.—The author). Now, it is universally admitted that these bacilli are omnipresent in restricted localities, such as certain hospitals, less so in tenement houses, cities, country towns, the country, and places which are uninhabited. This being so, why is it that attendants of such hospitals, physician and nurses, are no more likely to take the disease than the rest of the community? and why are these only liable to the extent of fifteen out of every hundred? The smallness of the bacilli and their omnipresence are certainly no barrier to their choice of habitat. The reason, then, why general infection does not occur, must not be sought for in the peculiarities of the bacilli, but in differences existing between the members of the human family. This brings us to the consideration of

The peculiar conformity of the lymphatics by which the occurrence of tuberculosis is facilitated.—In regard to this subject we may be permitted to quote Dr. H. F. Formad, of Philadelphia, whose paper read before the Philadelphia County Medical Society on October 18, 1882, deserves not to be buried in oblivion, which it stands in danger of, partly in consequence of deductions fully unwarranted as time has demonstrated, and partly because of the adverse criticism of Koch, whose authority was, and is even now, so great in investigations concerning bacteriology, that his *pro* or *con* decides the fate of offspring in this branch of medical science.

Formad says: "*The predisposition to tuberculosis in some men and animals, the so called scrofulous habit, lies in the anatomy of the connective tissue of the individual, the peculiarity being a narrowness of the lymph spaces and their partial obliteration by cellular elements.* The idea of working up the anatomy of scrofulous persons was suggested to me some years ago by the lectures of Prof. James Tyson. Dr. Tyson, in his lectures, as well as Virchow, lays great stress upon the predisposition to tuberculosis, and designates it as a peculiarity of scrofulous persons, that inflammatory processes in such persons terminate ultimately in the formation of cheesy matter at the seat of injury. The general impression among pathologists and clinicians is that the lymphatic apparatus is in some way at fault in these persons, although there are no direct anatomical observations on this point on record. I thought that the minute anatomy of the tissues of such persons should be investigated, and at once began to collect the necessary material.

I have here two specimens under the microscope to which I invite your particular attention, as they illustrate the histological difference referred to between the normal tissue of the rabbit and that of the cat. The animals, which are representatives of the scrofulous and non-scrofulous species, were of equal age, both healthy, killed in a similar manner, and the sections, which were taken from precisely corresponding parts, are equally treated and mounted I selected in this case the corresponding parts of the nose of the two animals It makes, however, no difference what part of the body is taken, as long as it shows some connective tissue The relative difference to be spoken of is equally striking everywhere in the two animals in corresponding parts of the body At the first glance it is seen in the specimen from the rabbit that there are a great many more cells in the microscopic field than in the corresponding field in the specimen from the cat Again, that the cells which are located in both cases between the interstices of the connective tissue are predominantly round and crowded in the rabbit, with only a few spindle shaped and stellate cells, while in the cat the cells are mainly of the latter two varieties, scattered and few in number In other respects the connective tissue proper appears similar in both cases The difference seen in the tissue of the rabbit and the cat exactly corresponds to a similar difference between the scrofulous human being on the one hand, and a normal individual on the other Repeated microscopic examination of well-selected cases has shown this Comparing a large number of sections taken from corresponding parts of the bodies of rabbit and cat, it is also distinctly seen that the lymph spaces are, on the average, decidedly narrower and fewer in the rabbit than in the cat The perivascular spaces are, however, equally free and similar in both

"The filling of the lymph spaces with desquamated and germinating endothelial cells, or with wandering—in white blood corpuscles, is a well known fact in the pathological histology of tuberculosis, but it does not seem to be known that this is a normal condition in the rabbit and guinea pig, and in scrofulous persons long before tubercular disease ensues

"The results of the observations above briefly narrated suggest the establishment of an anatomical criterion for the predisposition to phthisis Animals with this predisposition, viz the described anatomical anomaly constitute a well defined species, that of scrofulous animals The same anatomical anomaly is seen in men, and hence, I think, we are justified in classing all the scrofulous human beings as a pathological species of mankind The scrofulous condition being an anatomical anomaly, is thus not necessarily a pathological condition, and is by no means a disease in itself It has a perfect analogue in the domestic rabbit and the guinea pig The offspring of these scrofulous animals have the anatomical peculiarity of the connective tissue of their parents, they inherit it, and so do the offspring of scrofulous human beings"

It must not be forgotten that this condition, called scrofulous by Formad, can be induced in animals and men who hitherto have not possessed it, and that those who have *acquired* it may transmit it to their progeny It is certainly a clinical fact, that many people who are scrofulous—that is, have this narrowing of the lymphatics and accumulation of cells in them, never die of tuberculosis And again, that persons do die of this disease, who did not manifest prior to its establishment any of the criteria of scrofulosis Another factor, therefore, for the establishment of tuberculosis must necessarily be added, and this consists *in the porosity of the soil for the implantation of the seed, the bacillus*

Not all localities are equally accessible to the bacillus Observation shows that stratified pavement epithelium forms the most thorough protection to the underlying structures A recent author goes so far as to claim that gonorrhœa in the female seldom, if ever, proceeds from the vagina, but having been established upon the cervical membrane (cylinder epithelium) spreads thence to the adjoining parts, which may readily yield to medication, the disease, the gonococci, however, may still remain in the starting point, the uterine cervix, as a nidus not only for infection of parts more interiorly situated, but also for the urethral mucous membrane of the male, thus furnishing an explanation for the causation of gonorrhœa by females apparently well And just so the stratified epithelium of the mouth protects this from syphilitic, diphtheritic and tuberculous infection with far greater certainty, than the stratified columnar epithelium of the parts beyond Less resistance, of course, is offered by simple layers of epithelium of which the cylindrical variety is the least resistant We do not speak of traumatic lesions now, they may one and all of them be included in the category of accidental inoculations, productive, invariably so, of a primary tubercle formation and consequent general miliary tuberculosis, or of the latter at once, which difference is explained by the amount of material (baccilli and their spores) which has found its way into the circulation Of these things hereafter What concerns us now is the cultivation of the soil, i e the lungs, for the reception of the seed, and no conditions are better husbandmen than measles and pertussis, and their concomitant bronchitis And none exemplify our meaning better For in measles we meet with a form of bronchitis, which seems to affect the uppermost layers, the epithelia of the mucous membrane particularly So much so that smaller or larger patches of the epithelia die and leave raw surfaces exposed, open for the reception of almost anything—the bacilli of tuberculosis among others And indeed tuberculous ulceration of the larger bronchi would be far more frequent, were it not for a provision hitherto entirely overlooked—the protection offered by the elastic fibres of the internal fibrous layer, and *particularly by the circular muscle-layer, which may be crowded to death by tubercular growths, but never acts as their submissive host*

In pertussis we seldom miss the bronchitis, and as in measles so in this disease, the lymphatics and mucous and bronchial glands are drawn into sympathy, even to the extent of softening of the latter To this is added the spasm of the glottis which is overcome by the explosive cough, but seldom without injury to the mucous membrane of the bronchi, so that hæmorrhages, larger or smaller, from it, are of frequent occurrence Another factor established by the spasmodic cough is the squeezing of the fluid portion from the contents of the alveoli, leaving the dry debris behind, which simulate in their appearance the caseous matter of so called catarrhal pneumonia And acting as foreign substances upon the walls of the alveoli cause a proliferation and death of the alveolar epithelium, and thereby present a new surface, a porous soil, to the seed of tuberculosis This same result is reached in another way by capillary bronchitis, in which the inflammatory process of the smaller bronchi extends to the alveoli, giving rise to a deposit into them, which is composed of the usual inflammatory exudate and the multiplied epithelia and their debris, now called catarrhal pneumonia, a name not at all appropriate, and one which should be replaced by that of alveolar-bronchitis, for that is what its anatomical features proclaim it to be

Thusly another and very important requisite for the development of tuberculosis is furnished, namely *The undisturbed possession of the proper soil, for the the germination of the seed of the disease* For the spores of tubercles, like other seeds, in order to develop, must be bedded in or on the soil before they can grow and propagate Indeed, in the case of the tubercle bacilli it is absolutely necessary, as they have but one method of spreading, that of infiltration of the surrounding tissue Now no part of the body offers a better and more quiet retreat for these purposes, than the alveoli, withdrawn as they are from the performance of the respiratory function And it is just here that the importance of Dr Formad's investigations appears The contracted lymphatic spaces, already crowded with cellular bodies offer, or rather cannot offer any assistance to remove the material accumulating in the alveoli Nor can they permit the entrance into them, or the passage through them of matters accidently introduced into the burdened alveoli (For it is not an absurd supposition, by any means, to maintain the passage of bacillary spores, and bacilli even, through the lymphatics into the blood stream and thence by way of the kidneys out of the body) The lymph spaces, modified as they are in the scrofulous, do double duty, they assist in the retention of the product of the preceding alveolar bronchitis (alveolitis), and stand guard against intrusions upon the travail of the seed of tuberculosis That these things are absolutely necessary, is shown by a recent and very ingenious experiment by Prof Ribbert, of Bonn He quotes the observation of Lichtheim that a difference in the localization of ' mucor" and "aspergillus" exists That the latter by preference develops in the muscle tissue, whilst of the former only once a small focus was found by him in the diaphragm Prof Ribbert, knowing that the spores of mucor are very much smaller than those of aspergillus, subjected the spores of the former, with suitable precautions, to a process of hatching, by which they carried on outside of the body a part of their developmental phase In the course of twenty-four to thirty hours the microscope could detect a number of swollen and already germinating spores Such a preparation injected into the body would be followed by a great many foci of growing mucor in the muscles of the body The germs had become larger, and this was sufficient to retain them in the tissue through which they would have otherwise passed

Wesener finds that entirely different effects result when tuberculous sputa are injected into the intestines directly, or into the stomach by way of the stomach tube The latter process would be followed by varying results, and when tuberculosis did occur, it was found almost invariably in the mesenteric glands (rabbits) The injection into a loup of the small intestines, to the contrary, was followed by tuberculous ulceration of the intestinal wall itself Wesener thinks that by stomach ingestion, the bacilli are destroyed and the spores only find their way into the intestines, and are not lodged until they reach the mesenteric glands, where they develop, but when the sputa are injected into the intestines directly, the bacilli at once commence their deleterious work upon their walls

The frequent occurrence of the latter form of tuberculosis in patients sick with the same disease of the lung, may then be explained by the quantity of sputa ingested, by the weakened stomach digestion often noticed in such cases, the possibility of an advanced development of the spores, which find their way into the intestines, the anatomical changes described by Formad, and finally by traumatic lesions in the intestinal mucous membrane, caused by the cough, and other influences, not to speak of the loss of resistance of the tissues, presently to be mentioned All these things being granted, another factor for the lodgment of spores and bacilli of no small importance must be considered *The carriers of the poison*

For a full comprehension of this point we may be permitted to again refer to Prof Ribbert's paper, above alluded to Injections into the vein of the ear of a pure culture of staphylococcus aureus would be followed occasionally by very small foci of this bacterium in the heart muscle Prof Ribbert varied the experiment by scraping some of the potato upon the surface of which the staphylococcus had grown, and formed an emulsion of the two, which he then injected into the vein of the ear, the result was a multiple embolism caused by the potato, in the substance of the heart, and a growth of fair dimensions of the staphylococcus The particles of potato furnished a stopping place for the bacterium, and its subsequent development Thusly our position, that the bacillus of tuberculosis must have a resting place, is corroborated by the experiments of other observers for bacteria of an entirely different character, and we repeat, that no place seems more propitious than the alveolus, withdrawn from the functioning part of the lung, provided however, that it furnishes *the food necessary for the development and propagation of the bacillus* And this food is supplied in the following manner In the first place it cannot be doubted, that the material contained in the alveoli, composed of the factors of the blood, and the epithelial cells of the alveoli furnishes a nutritive medium of superior quality the efficacy of which is enhanced by the proper temperature, and this very food prior to its exhaustion by the bacilli, has opened the way to further supplies by its influence upon the adjacent tissue, pressure has brought the resistance of this down to a minimal, to be readily overbalanced by the advancing hordes of the enemy, it falls a ready prey to the bacilli, multiplied and fattened upon the contents of the alveoli

But the pressure of the deposit in the alveoli is not the only cause of the lessened energy of the surrounding tissue elements Here again the conditions described by Formad will spring into view It needs scarcely a mention to him who knows, that the facility with which interchange of material in the tissues takes place, governs materially the vitality of such tissues No one can fail to see the crowded and narrow lymph spaces, without observing at the same time the stunted blood capillaries, even the surface of such tissue shows the starved condition of it, by its paleness and flabbiness The very treatment of such parts by the physician and the surgeon demonstrates the low vitality inherent in them The tuberculous membrane of the pharynx receives stimulating applications by the former, whilst the latter irritates the tuberculous joint by blister and rubefacient, fully cognizant of the fact, that *rest*, the alpha and omega of the treatment of inflammation (over nutrition) is worse than useless in these cases

In connection with this part of our subject, it would be an unpardonable oversight not to mention the part played by the cells of the body, which Metschnikoff calls phagocytes (the amœboid cells and leucocytes) upon the one hand, and the fungi upon the other "The phagocytes retaining their original character of intercellular food reception, act through it as the exterminators of the parasites, and appear therefore as representatives of the long since known healing power of nature, which was first placed by Virchow into the tissue elements" He continues to form an analogy, and with good reason, between the occurrences in the disease of the daphnia and tuberculosis, and concludes "That also in tuberculosis, against the cause of the disease, a battle of the phagocytes rages, through which the organism often for a long time resists, and in some instances conquers" Thus every phase of the history of tuberculosis puts into prominence the importance of the scrofulous condition of the tissue Yes, even the treatment of a person, sick with tuberculosis of the lung, as taught by experience, assumes the necessity of restoring the greatest vitality to the patient, attainable by him And what does this mean more than the restoration to their normal vigor of the component parts of the body

That tuberculosis may occur anywhere in the economy wherever connective tissue and lymphatics exist, goes without saying, and that the cause of the disease, the bacilli and their spores, may and do find their way into the tissues by channels at all conceivable, is a statement warranted by experience Yet this important point must not be overlooked, that tuberculosis is always a local disease, spreading by progressive invasion, and that general miliary tuberculosis is caused, with exception of its direct (artificial) introduction into the blood stream, by the discharge of the contents of localized foci, either into the thoracic duct or the blood stream This takes place by the intervention of softened glands upon the one side, which empty their contents into the thoracic duct and thence into the circulation, or by a breaking of the softened mass from the glands into the blood stream, by way of adjacent veins, the walls of which have been destroyed by the same cause C Weigert found, in thirteen out of fourteen cases of acute miliary tuberculosis, the place where the softened mass had broken into the general circulation, or into the thoracic duct

The writer has several times followed the course of local infection to the development of general tuberculosis and death The last case was particularly instructive It concerned a young man, rather intemperate, with all the evidence of a weakened vitality, with no family history of tuberculosis, who had a tooth drawn by a dentist Several days after the extraction, intense pain in the tooth cavity took place, which was eased with anodynes Several weeks later the submaxillary glands became enlarged and some eventually discharged their contents exteriorly By this time a sinus was established from the tooth cavity to the surface below the angle of the jaw I advised extirpation as the only means of hope, this was refused, and local applications ordered by consultants The final issue—miliary tuberculosis and death—and all this in less than six months Now an easy solution of this case is offered by the supposition, that the dentist's tools were infected with the tubercle poison by previous use—the writer will have to see the first dentist yet who seems to have heard anything of antiseptic surgery A drying with a towel of the instruments used, after they have been rinsed in cold water is the full extent of the precautions against infection usually taken I do not at the present writing remember of reading anywhere anything regarding the danger from dental surgery And yet it seems greater from the very proximity to the sources of infection, as well as the nearness of the submaxillary and deep lymphatic glands to the thoracic duct, and the general circulation I know that the road to general tuberculosis by way of those glands, is the nearest that can be traveled Now that attention has been drawn to this source of infection, who is it in general practice who does not remember just such cases, and shall he not join the writer in sounding the alarm?

(*To be concluded*)

ENLARGED CERVICAL GLANDS[1]

BY HERMAN F VICKERY, M D,

OF BOSTON

The object of this paper is to arrive at definite and well-grounded opinions as to the treatment of what is sometimes called "scrofulous neck" These cases present enlarged lymphatic glands in the neck, causing little inflammatory disturbance or pain, as a rule, but very chronic, and tending to break down into cheesy pus Exceptionally, complete resolution takes place, more often, fibrosis or calcification, but in the great majority of cases, sooner or later, arises an abscess which discharges through a sinus, the sinus emitting pus more or less constantly until the entire gland has been thus expelled Although there is not much suffering, yet the tediousness of these cases, which may persist for years, the unsightly appearances caused both by the glands and sinuses and by the scars they leave behind, and above all, certain dangers hereafter to be more fully discussed, render it desirable that the best possible treatment should be employed for them

---

[1] Read before the Section for Clinical Medicine Pathology and Hygiene of the Suffolk District Medical Society January 13 1886

We find the disease prone to attack children much rather than adults, although even old age is not absolutely exempt All debilitating, hereditary, or hygienic conditions predispose to it, its chief victims, therefore, are the children of the poor and ignorant, or of consumptive or syphilitic parents Overcrowding, lack of sunlight, insufficient and improper food, exposure to cold and wet, all promote its occurrence Out of 172 children who entered a workhouse in Kent, England, healthy, all but three came to have enlarged glands The exciting causes are very numerous, comprising such lesions of the mucous membranes as ozaena, stomatitis, tonsillitis, pharyngitis, laryngitis, otitis, and conjunctivitis It may follow chronic eczematous processes in the scalp or face It frequently arises after scarlet fever and measles, and may be excited by dentition or by trauma It is characteristic of this form of adenitis that, although supposed to be invariably secondary, its extent and persistence frequently far exceed those of the primary lesion It is often impossible to determine what did give rise to the glandular disorder

In early stages, the enlarged glands are freely movable upon the underlying tissues and underneath the skin They are smooth in surface, of uniform density, and more or less spherical It is seldom that a solitary gland is swollen, usually two or more are affected The affection is not essentially symmetrical, it may be bilateral After continuing a variable length of time with but little change, the gland may, as has been said, be absorbed Such a result is especially likely at puberty The rule, however, is that the tissues undergo what is called a "cheesy" degeneration This can usually be recognized during life by the nodular surface of the gland, its presenting spots of softening or fluctuation, and its adherence to the skin as well as to neighboring glands, if they also are enlarged A rare termination for this cheesy transformation is spontaneous dessication and calcification Almost always there is gradually increasing suppuration, abscess formation, and external discharge through the adherent skin About the histological changes, I wish merely to state what seems essential to forming a just view of the dangers and treatment of the disease Schuppel, of Tubingen, published in 1871 a book on "Tuberculosis of the Lymph Glands," in which he shows that a large proportion of what are called "scrofulous" glands—although not all—present the microscopic characteristics of tubercle, that is, one or more giant cells surrounded by epitheloid cells and lymph corpuscles, the whole supported by a fine recticulum Klebs produced, by the inoculation of tuberculous matter, a disease of the lymph glands exactly like scrofulous infiltration Koch reported, in 1884, that he had examined twenty one cases of tuberculous glands (meaning such glands as presented epithelioid cells grouped in foci, and accompanied by more or less numerous giant cells), and that he invariably found bacilli tuberculosis in them There were indeed, other enlarged glands, in part softened and dotted with minute abscesses, but with no epithelioid nor giant cells, in which he found no bacilli From the submaxillary gland of a scrofulous boy he obtained pure cultures of the specific tuberculous bacilli Dr Hippolyte Martin also produced a series of cases of general tuberculosis in guinea-pigs, starting from the inoculation of pus taken *post-mortem* from the "firmly encased submaxillary gland of a child who had died of measles and broncho-pneumonia, without any trace of tubercular disease, but with well marked clinical characteristics of scrofula" It may therefore be affirmed of enlarged cervical glands, such as are ordinarily called scrofulous, that certainly a large proportion of them, and probably a large majority, are really tuberculous

As already stated, the existence of scrofulous lymphatic glands usually implies that the general health has been impaired The local disturbance is seldom very annoying The condition is often discovered by accident Occasionally there is some pain and tenderness, particularly if suppuration is taking place By its mechanical pressure, a gland, or a collection of glands matted together, may give rise to compression of the carotid or jugular, the trachea or œsophagus, the recurrent laryngeal, sympathetic or vagus nerves Epistaxis is sometimes caused by them, and even fatal suffocation

It is seldom that diagnosis is difficult Acquired syphilis may cause induration of the cervical glands, but the enlargement is less, the tendency to cheesy degeneration is slight, and we should find other venereal symptoms A simple adenitis, such as might, for example, follow traumatism, is more acute It exhibits more inflammation, and either resolves or suppurates much sooner than a scrofulous gland Pseudo leukæmic glandular enlargements are more or less universal throughout the body, that is, in the axillæ and groins and at other points, they grow more rapidly, do not break down, and are accompanied by marked anæmia and debility Glanders and farcy could hardly be mistaken for mere scrofula, if the physician exercised any care whatever, and the same might be said of bronchocele Cystic and other tumors may occur in this region, but are comparatively rare, and their differential diagnosis can be learned in works on surgery

"The scrofulous patient," says Allbutt, writing on the treatment of scrofulous neck, "runs three risks in the continuance of his local malady over and above his faulty inheritance, namely first, a tedious local disease followed by a peculiarly unwelcome disfigurement, secondly, the fear of deterioration of his general health thereby, such that his best years of adolescence are spoiled and his entrance into manhood thwarted and weakened, thirdly, an inoculation of the system with elements which favor the development of more general tuberculosis"

In the early stages it is quite possible that a gland may be absorbed if the general health be built up Local applications may also promote the same result, but we shall revert to this point under treatment When once nodulation, softening and adhesions have begun, the cheesy process is under way, and it seldom ceases before the gland is totally necrosed and discharged A fibrous or calcareous transformation of the gland is, however, possible, as is also absorption even now A further and more important consideration is the effect upon the general health, if the glands are tuberculous Friedlander, in his familiar lecture on "Local Tuberculosis," states that although the process is malignant, it is not apt to become diffuse Out of 332 cases of phthisis, Philips found, *post mortem*, "scrofulous scars" in but seven Again, out of 1,078 autopsies of consumptives, less than one per cent showed evidence of cervical gland disease Says Treves, in his work on "Scrofula and its Gland Diseases " "While scrofula and phthisis are manifestations of the same morbid process, I am nevertheless convinced that phthisis is by no means common in the scrofulous, and that the bulk of such patients do not die of pulmonary consumption " And as to the danger of acute miliary tuberculosis, Treves does not think it very great, although he would not be entirely indifferent to it On the other hand, Rindfleisch believes that "tuberculosis hardly ever appears except in scrofulous persons " Lynch affirms that "The products of decay resulting from scrofulous processes may enter the circulation and directly produce the tuberculous dyscrasia " Further remarks about prognosis will be made incidentally under Treatment, which is the next and final topic

The first indication to be met is, of course, to allay all causative disorders, such as eczema, rhinitis, pharyngitis and the like The general health next demands attention In the first place it is usually depraved Secondly, if the patient be in a state which offers the bacilli tuberculosis a favorable nidus so far as the lymph glands are concerned, why may we not justly fear that predisposition to tuberculosis pulmonum also exists? Either ground is sufficient basis for vigorous tonic treatment Fresh air should be obtained for the patient, either at the seashore or in the mountains or in the country For dwellers near the coast it would seem more natural to choose the interior Sunlight, moderate exercise, simple but nutritious and abundant food, salt water baths, and such analeptics as cod liver oil, iron, arsenic or iodine, —all these should be simultaneously brought to bear upon the case

If glands are already cheesy, we may be tolerably certain that a lingering, disagreeable and disfiguring process will go on for months and perhaps years, unless the necrotic tissues are removed by operation Experience has proved only too clearly the inefficiency of external applications, while surgical removal has been found to be very satisfactory and comparatively easy For example, Billroth, Treves, Fagan, of Belfast, and Teale, of Leeds, all express themselves as pleased with the results of extirpation

About the treatment of cases still in the first stage there seems to be more room for difference of opinion Let us make sure, before we form our own, what we would like to obtain for a local result Friedlander makes the following therapeutic deductions at the end of his lecture already referred to It is desirable to remove tubercles where it can be done without danger, because (1) they are fated to destruction, and until they are removed recovery cannot be perfect; and (2) by such removal we destroy a source of at least local infection On the other hand, he proceeds to say, we should only very exceptionally undertake any serious operations which cripple or deform the patient, just on account of local tuberculosis because, (1) constitutional infection is not inevitable, and (2) spontaneous recovery is possible Schuppel quotes with warm approval the dictum of Virchow that "it is certainly justifiable to remove as early as possible such tuberculous organs as can be easily reached If operation seems impossible or undesirable, then we should at least hasten suppuration and free discharge" Treves, in discussing treatment, declares "Out of the enormous number of patients who present caseous deposits in their bodies, the percentage of those who fall victims to diffused tubercular disease is so very small that the probability of that disease may be put out of the question I think also," he continues, "that the argument advanced by Ruehle in favor of removing glands on the plea that such removal may prevent phthisis is unworthy of consideration in discussing this mode of treatment," that is, by excision These opinions seem to differ considerably, but certain deductions can be made from them There is an acknowledged possibility of constitutional infection from strumous glands The virus, if it becomes thus generalized, can only do so by way of absorption It is then pertinent to inquire, Why endeavor by external applications to promote resolution of enlarged cervical glands?

Very likely we all breathe daily into our lungs the bacilli of tubercle, and yet do not become consumptive, because, presumably, our bodily condition is such as repels the invader But the sufferer from tuberculosis of the cervical glands might, as has been seen, naturally be supposed to exhibit a predisposition to tubercle If, by invigorating his system, we get him into such a state that nature of her own accord absorbs the disorganized tissues, we may be content; for she probably will do it with impunity Experience shows that this is often the case It does not, however, commend itself to my judgment to seek, even in the first stages of the malady, by local irritation, such as the application of various forms of iodine, or by blisters or electricity, as some recommend, to excite an artificial resolution, if I may so express myself It may be added that the attempt is often futile If *general* stimulation fails, then we should resort to extirpation

The only occasion which seems to me to call for local application is where there is pain, heat and swelling, and as yet no certainty that suppuration has taken place Such glands should be treated with a cooling wash until they either abate or else present clear signs of pus

By first improving the general health there will little time be lost Possibly some or all of the glands may be absorbed If not, operation will take place under much more favorable auspices

Glands which are in the first stage and freely movable can be quite readily cut out. The incision should not be very long. Violent tearing of the surrounding tissues, besides other things, brings danger of troublesome periadenitis. The cheesy glands (which are nodulated, or have perhaps suppurated and are fixed to the skin and to each other) are usually best extirpated with a spoon. Treves has found the thermo cautery very serviceable. In cases where a subcutaneous abscess has formed it is often a much more ready than satisfactory method to make a simple incision. Pus should indeed be evacuated without delay, but a careful search will quite frequently discover a sinus leading from this superficial abscess to a cheesy gland deeper in, which itself must be eradicated. Teale praises Bigelow's sinus dilator for such operations. Antiseptic precautions are advisable and iodoform makes a good dressing. Drainage is usually necessary. Healing is promoted by obtaining rest for the parts, as by a leather or gutta-percha stock, outside the bandages.

The different manifestations of scrofula are said to be somewhat antagonistic to each other, so that "the particular scrofulous malady any given patient presents would appear to protect him from any other outcome of the disease for at least the time being." This need not, however, prevent operation, for there is practically no danger that the eradication of scrofulous glands will indirectly excite caries or tumor albus and the like elsewhere.

SOME OBSERVATIONS ON HEALTH RESORTS[1]

BY E. O. OTIS, M.D.,

OF BOSTON

It is not with the expectation of presenting anything new upon the subject of health resorts, that I write these few notes, but rather with the hope that possibly I may render some aid, by means of the following suggestions and record of personal observations, limited though they may be, to the family physician who is called upon, as so often unfortunately he is, in this climate, to recommend a proper resort to patients suffering from pulmonary troubles, for they compose the majority of those who seek a new clime.

The subject of climatic cure is a many-sided one, and there are many and diverse opinions as to what constitutes a suitable resort for those with delicate or diseased lungs. I have only to refer to the excellent paper of Dr. Harold Williams, in a recent number of the *Boston Medical and Surgical Journal*, to show the variety and conflict of opinions which exist upon this subject. The general fact, however, remains that thousands have had their lives prolonged or saved by a timely resort to some one of the many places in this country, more favored by nature as to climate than this bleak New England coast.

I am not a partisan of any special portion of the country or any place, as a universal elysium for all those afflicted with lung trouble. On the contrary, I believe that each individual case should be carefully considered in all its aspects, and be sent to that place and climate which seems best to meet its own especial needs and requirements.

One person has little vitality and is always pinched with the cold; such a one obviously will do better in a moderately warm climate, like Southern California or Florida. Another case will endure a certain degree of cold, and will thrive in a locality of lower temperature, like Colorado or Asheville. Again, the digestion may be at fault, and it is of primary importance that a place should be selected where a good table may be depended upon, even if something has to be sacrificed as to the climate. Moreover, the mental condition and temperament must not be disregarded, and the kind of life the patient has been leading. One person requires much diversion, and would be wretched in a quiet, secluded place, but contented and happy in a more lively one, like St. Augustine, for instance.

Companionship is also an important element, and with pleasant, genial associates, one will often make greater gain in a less favored locality, than with the lack of them in one more nearly approaching the ideal climate. The opportunities which different resorts offer for varieties of exercise are not to be lost sight of, as well as the favorite form of exercise of the patient. Happy and fortunate is the consumptive, as well as any other man, who has a hobby which will give him exercise in the open air, be it fishing, gunning, rowing, or horse back riding. I believe that the cause of many of the unfavorable results in cases which have been sent to health resorts of acknowledged worth, is the neglect of carefully considering all these factors.

Of course, it goes without saying, that due attention should be given to the hygienic condition of the locality determined upon, and also, that the fundamental principles of all health resorts are to be borne in mind, namely: Pure air, dry soil, and abundant sunshine. Elevation, dryness, and equability are often, I believe, of secondary importance, and are to be taken into account rather when the requirements of the individual case are being considered.

There should be at hand, also, in every health resort, a reliable physician, with whom, if necessary, the home physician can communicate concerning his patient.

I am of the conviction, as I believe all are who have given much attention to the matter of climate, that the best results are obtained by as long a continuous residence as possible in the place and climate which has been found to suit the case. It takes a long time to become acclimated if the change is at all radical, as from a cold to a warm climate, or from a low to a high elevation, and after that, comes the benefit and improvement, and so long as that continues, it is better to remain in the chosen resort.

Still, there are many whose conditions and circumstances are such, that the stay away must be limited, and the number of places from which to choose, restricted. In order, then, that the most good may be accomplished from the time allowed, all the greater care must be given in the selection of the resort from among the ones possible to the case in question.

---

[1] Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, January 13, 1886.

Indeed, so many points have to be thought of in choosing a new home for the man of weak lungs, that I have almost come to the conclusion that no physician has any right to advise a patient to go to this place or that, unless he has first visited it himself and thoroughly investigated its advantages and defects. Recently, a young lawyer came to me and related his experience in being sent to a health resort. After it was determined, from the condition of his lungs, that he must go away, the advice as to a new climate was something in this wise: "Some say this place is good, others that, I know nothing of any of them. You may find the Tennessee Mountains of benefit, but I know nothing about them, have never been there, you can go and try them." So he went, and after numerous vicissitudes, he fell to living a complete out door life, much of the time on horse back, and came home apparently well, and has remained so for several years. Such hap hazard advice, however, will not always have such fortunate results.

"Happy the patient," says Youmans,[1] in a recent article on "Thomasville as a Winter Resort," "advised to change his climate when the physician knows enough to give him intelligent instruction as to whither he shall proceed. Does he need a milder or high temperature? a damp and relaxing, or a dry and bracing air? an inland location or the seaside? a valley or a mountain? Should he try Bermuda or Aiken, or Nashua or St. Augustine, or Asheville, or any of the score of resorts recommended for pulmonary invalids? If the doctor settles the point, it is well, if not, the patient must take his chances, and do the best he can to settle it for himself." Going on to relate his own experience, he says: "With lungs badly out of order, everybody said I must escape the severities of a New York winter by going somewhere. I advised with several eminent pulmonary experts, who agreed that it might be a good thing to get away, but did not seem to think it made much difference where I went."

If specialists continue to multiply, perhaps in the future we shall have the specialist on climate. One who has visited the different health resorts and made careful observations, not only as to any particular climate, but of all the accessories of the place—food, sanitary condition, means of exercise and amusement, manner of reaching it, and so on, and who, moreover, will give an unbiased opinion, instead of the half truthful, exaggerated reports which local partisans give of the place they are personally interested in. In a pamphlet before me, just received from Thomasville, Ga., I quote the following as illustrative of this exaggeration: "The fact is well recognized that a damp atmosphere is what a sufferer from pulmonary trouble should avoid, and it follows, that to obtain the greatest amount of good effects from the presence of the fragrant pines, the breezes that waft the balsamic odors abroad must be dry, and themselves inodorous. In order that these conditions be fulfilled, it is essential that large quantities of water be absent, and the surface of the country be high and rolling. A fulfilment of these conditions is impossible in Florida, surrounded, as the State is, *on three sides by the ocean*, with its land surface but a few feet above the level, a dreary waste of interminable swamp, intersected by sluggish streams and marshy lakes. Perched on her elevated position, Thomasville can lay claim to the advantages of *a dry climate and thorough drainage*, and her claims have secured the recognition of the most eminent physicians of the country who have made pulmonary troubles a study."

Again, in an article entitled "Marion County, Florida: An Ideal Winter Climate," by Dr. Maxwell, of Ocala, published in the *Medical News* of December 19, 1885, the author, among a number of very loose statements, makes this assertion: "It is capable of demonstration . . . that Florida possesses the essentials (of an ideal winter climate), in a higher degree than any country now known," and as a part of this demonstration, he introduces a table of mean relative humidity, compiled by Dr. Kenworthy, from the inevitable Signal Service Reports, which shows, he says, "that Jacksonville, in the matter of dryness of air, compares favorably with the popular resorts in all parts of the world," the table given, containing the names of thirteen places only, three being in Minnesota, three in Florida, two in France, and one each in Nassau, New Jersey, Georgia, Dakota, and Massachusetts. If the Doctor had included Denver, for instance, in his list, he would have found its relative humidity some seventeen points lower than that of Jacksonville.

I will now give some notes and bits of information upon a few health resorts I have visited in the South and elsewhere, and I trust I shall be pardoned if I seem to give some petty details, even to the noting of boarding houses, for such information is often of much assistance in settling the perplexing question of a new home and climate.

The Southern resorts can roughly be divided into those of the coast, interior, and mountains, and with the exception of the latter regions, are generally regarded as winter homes for invalids, but the rule of continuous residence, before mentioned, will hold good, I believe, even of many of these Southern localities. The mountainous regions, embracing the Alleghany, Blue Ridge, and Cumberland Ranges, are considered more appropriate for the milder portions of the year, but here, again, I would advocate the above rule for, at least, portions as far south as Asheville, unless the idiosyncracy and condition of the patient were such as to forbid a moderately cold climate.

Of the coast resorts, places on the East or West side of the Peninsula of Florida are, perhaps, more generally selected, and whether the Atlantic or Gulf of Mexico shore is the more favorable, seems to be a matter of opinion. As the prevailing winds are East, it is said that the Atlantic coast gets the purer air direct from the ocean, while it reaches the Gulf coast after blowing over the peninsula, and is, in consequence, more or less vitiated. Of course, the climate of all sea coast resorts is a more or less moist one, which, in adapting a climate to the individual case, is a factor to be considered.

---

[1] Popular Science Monthly, December, 1885, page 188.

One fact I desire to emphasize, and I might as well mention it here, namely, that, in my experience it is exceedingly difficult to obtain good food in the South. The meat and bread are poor, as a rule, and the coffee, with few exceptions, execrable, and from the fact that there is very little grazing, the milk is poor, if, indeed, it can be obtained at all. The houses where good board is obtained are generally kept by Northern people.

On the Atlantic coast, St. Augustine is the best-known resort, and it has much to recommend it. The soil is sandy, and the days, so far as my experience goes, are generally sunny and delightful. The mean temperature is 58° in the winter, and 68° in the spring. The number of clear days for the whole year is said to be 235, which I should very much doubt. Artesian wells have recently been sunk, and the city is now supplied with good water in place of the surface water formerly used. It is an attractive place on account of its picturesque, quaint architecture, the old fort, sea wall, and barracks, and the presence of a military band adds much to the pleasure and entertainment of the exile. There is also good sailing and pleasant water excursions.

If I may be allowed to give a couple of names, I will say that any one who can obtain accommodations at Miss Hasseltine's on St. George Street, and have for his medical adviser Dr. Adams, will be well cared for. As to malaria, I have not much doubt as to its existence pretty much all over the South, but I saw very little evidence of it in St. Augustine.

If one desires to go still farther south on the Atlantic coast, the little town of Daytona on the Halifax river, was highly extolled to me for its agreeable climate, by a resident of the place.

Going over to the Gulf side, I will speak of Tampa, reached by railroad direct from Sanford. In itself, it is not very attractive, the streets being very sandy, which renders locomotion uncomfortable. The bay, however, is delightful, and the excursions upon it, and up the Manatee River, and to Egmont Key are charming. So far as one's sensations go, the air seems delicious.

Bordentown, on the Manatee River, seemed to be a quiet, pleasant retreat. I believe it is on the Gulf coast, a little way from Tampa that a location for a sanitarium has been recently selected. On the line of the railroad going from Sanford to Tampa are many attractive places in the pines, Orlando, Winterpark, Longwood, Altamont, and Kissimmee, the latter prettily situated on a lake of the same name. Many find health and comfort on the St. John's River, but it seems to me that malaria must be more prevalent there than in places away from the river.

Anywhere in Florida one is pretty sure to find conditions under which he can lead an out door life, *which answers* one of the primary requisites for a health resort. Still the low, and in many portions, swampy character of the soil is a serious objection to its choice as a health resort in many cases.

About twenty miles inland from Charleston, S. C., is a resort much in favor with the Charlestonians, called Summerville. It is far enough away from the coast to escape the frequent east winds, and has a mild, equable temperature. It is in the midst of the pines, and has a pure air and sandy soil. From my experience, however, one must have a good digestion if he would gain any benefit from a sojourn here. There is frequent daily communication with Charleston, and the diversion of a run to the city is an added attraction to the place.

Fortress Monroe or Old Point Comfort does not seem to me to be altogether favorable for a continuous residence, but rather for a limited stay in the spring or autumn. The soil is clayey, the weather uncertain, and fogs are frequent. This opinion is fortified by that of one of the military surgeons whom I met there. The exceedingly attractive and unique life which one finds there, however, and the many excursions by land and water mitigate very decidedly the unfavorable climatic conditions, and succeed in drawing the patient out of doors and out of himself. The peculiar Indian summer days which are frequent there are particularly soothing and restful. For those who cannot afford hotel prices, and who desire greater quiet and seclusion than can be obtained at a large hotel, I will give the name of a good boarding house, the only one in fact on the reservation. It is that of Mrs. Eaton, near the water and opposite the Fort. On the Hampton river, opposite the beautiful grounds of General Armstrong's Normal Institute and the Soldier's Home is the boarding house of Daniel Cock, of good report, where there are good opportunities for rowing. It is, however, too far away to allow one to enjoy the diversion which the Fort life offers.

To jump from the South to the North, I wish to say a few words in conclusion, upon the Adirondacks, where patients not only spend the summer, but quite a colony now the winter. Dry it is not, judging from my experience the last summer, and the diurnal variations of temperature are quite great. But despite all this, so far as my observation has extended, consumptives do remarkably well there, provided there are no very acute symptoms. The air is bracing and pure, and the out door attractions numberless. Everything conduces to keep one in the open air, and persuades to much exercise. The grazing is good, and consequently the milk is abundant and rich. The boarding houses are often poor, but good ones can be found, as all who have made trial of the Mirror Lake House, at Lake Placid, can testify. I do not know that it makes much difference where one goes in the Adirondacks in the summer; perhaps the portions of about two thousand feet elevation are the best. If one is strong enough, and the digestion is good, camping out probably gives one more pure air than can be obtained in any other way.

Saranac seems to be the winter home for consumptives in the Adirondacks, and has the sanction of Drs. Loomis and Trudeau. It is better protected from the winds than other places, and commands a good physician. Near by the village of Saranac is the sanitarium recently established—a most admirable charity. It consists of a large main building and several cottages and tents, and, at a small price, one can obtain every needed comfort. The only objection, if it is one, is bringing together, in such close proximity, a number of consumptives. This did not seem, at least, to have a depressing effect, judging from the cheerful appearance of those I saw there. The sanitarium is kept open all winter, and I have at hand a letter from a lady who has been an inmate of the institution all summer, who wrote me that she has gained so much she proposed to spend the winter there. It was quite noticeable how many began to gain in weight after coming to the Wilderness.

I do not want it understood that I ignor the numerous other health resorts I have mentioned, or consider those I have the best; I have only spoken of the few I have happened to be personally acquainted with. I doubt not that there are many others far more ideal than any I have mentioned. All know of the remarkable results of the Colorado and New Mexico climatic cure, and of the influence of the climate in certain portions of California, and of the high pine lands of the South, as represented by Aiken; indeed, I think we have in this country a wealth of health resorts from which to choose. I desire, however, to emphasize the fact that there are many other considerations to be carefully weighed in selecting a resort for a consumptive besides the one of the best ideal climate; in fact, that is the best ideal climate for the individual patient which best meets his individual needs, mental and physical. And that in any place where the air is pure, the sunshine constant, and the temperature so adapted to his condition that he can live out of doors, he will improve if improvement is possible.

I will very hastly run over a single case which I think well illustrates the points I have been attempting to make clear in this paper.

In March of last year, I discovered, to my great surprise and alarm, that a member of my family had evidences of consolidation at both apices, accompanied with a moderate rise of temperature. Distrusting my own judgment when thus personally interested, I sought the opinion of Dr. Knight, who very kindly gave it, but corroborated my worst fears. In addition to the pulmonary trouble, the vitality was low, and there was much dyspepsia of many months' standing. The outlook indeed seemed dark, the prognosis grave. Many weeks of trying weather still remained, and I determined that an immediate change of climate was imperative, and that the harsh spring winds must be avoided. The first requisite was such a climate as would enable one to exist with the least exertion, and lead an out-door life. Moreover these conditions must be obtained with as little outlay of strength as possible on the part of the patient. I therefore went with my patient to St. Augustine, reached from Washington in about a day and a night. There I found delightful weather and sunny days, where a delicate person could live out of doors from morning to night, with perfect comfort. Damp no doubt it was and low, far from an ideal climate for a consumptive one might say, but it exactly fulfilled the conditions required for the patient in question, and before the month of April was over, she could walk about the old town, and take a lively interest in what was going on, whereas on her advent, she could hardly get across the street, and was indifferent to surrounding scenes. The lungs remained much in the same condition, to be sure, but the strength was returning, and the drooping spirits had revived.

At the beginning of May, we gradually retraced our steps North, following the strawberries. At Charleston it was the season of roses, and out door life was delightful. Every day brought an excursion with it. Add to this, pleasant companions, and again, we had an ideal climate for the especial requirements of this especial case. Loitering along we finally reached Fortress Monroe in its pleasantest season, and here several weeks were spent with benefit to body and mind. Now it seemed to me that the general condition had so much improved that a more bracing climate might with safety and benefit be tried, so our next move was to Lake Placid in the Adirondacks, 2000 feet above the level of the sea. My hopes were realized. From 103 pounds, the weight went up to 120, the dyspepsia almost entirely disappeared, and the consolidation began to clear up. So much had been gained at the end of October that it seemed to me still more might be ventured, and after an interim of two or three weeks, my patient went to Colorado, where she now is, and from whom I have the most encouraging reports of her well being and steady improvement.

MEDICAL PROGRESS

Viburnum Prunifolium in Abortion.—Dr. W. Macfie Campbell, of Liverpool, says: Since the publication of Dr. Wilson's paper in the *Liverpool Medico Chirurgical Journal* of January, 1885, I have had the opportunity of testing the use of viburnum prunifolium, so much vaunted in America, in several cases of threatened miscarriage, and I can entirely endorse the good opinion he has formed of it. Nothing, probably, in midwifery is more disappointing than the ordinary routine-treatment of miscarriage by opium or Indian hemp on the one hand, or ergot on the other. For these drugs as often act in the way contrary to the prescriber's intention as in accordance with it. How often has a dose of Battley's solution, administered to arrest uterine action, and give rest and ease from pain, been followed by immediate and severe expulsive pains, while the attempt to empty the uterus by a dose of ergot has resulted in a perfect calm, and a disappearance of symptoms.

It is a comfort thus to have some hope of success in dealing with such a condition as miscarriage; and although I have so far only the notes of six cases, of which five were successful, yet, these five being consecutive, and the effect exactly following the administration of the remedy, I have no hesitation in my own mind in giving the credit to the viburnum. The case of failure was my first.

Case 1.—Mrs. B., two months pregnant, had discharge of blood, with uterine action. She was treated in the usual manner, with opium and rest for two days, when extract of viburnum, in two grain doses, three times a day, was ordered. There seemed no effect upon the pains, the os continued to dilate, and the uterus was soon empty. Perhaps the dose was too small[1], at any rate, I had lost two days, which I take to be the reason of the failure

Case 2 —Mrs H , pregnant for the seventh time, two months and a half, was awakened by a gush of water early one morning, followed by a bloody discharge On examination, the os was soft and dilatable She was kept in bed, and given at once three grains of extract of viburnum every four hours There was no return of bright blood, and the discharge gradually ceased The relief to the pain after the first dose was in this case very marked

Case 3 —Mrs B , in her sixth pregnancy, one night during the fifth month was awakened by the "breaking of the waters," the escape being sufficient to saturate her night-dress and bedclothes This was followed by pains I saw her in the early forenoon, and gave three grains of the extract three times a day, and there was no further symptoms

Case 4 —Mrs G , in the fifth month of her second pregnancy, had a bloody discharge, with uterine pains The same dose was used, with the same good result

Case 5 —Mrs W , in the second month of her sixth pregnancy, had already had two miscarriages Two grains of extract of viburnum, three times a day, gave relief, as also a month afterwards, when the same threatening symptoms appeared

Case 6 —Mrs S , first pregnancy, fourth month This case was particularly interesting from the fact that miscarriage had been imminent in her case at each monthly period The first and second attacks occurred in America, when she was given viburnum, and her medical man provided her with a large store of the liquid extract, which he told her was unknown in England She had an attack at sea, and in due time in Liverpool, and was pleased to discover that the drug could be taken in pill, and was equally efficacious, as the liquid extract is very nauseous While I was from home she had another attack, in which she was attended by Dr Westby, who considers she was only saved from miscarriage by the viburnum During this last attack, she took her pills five and six times a day, in fact, her faith was such, that she would have taken too many Bromide of potassium was also given to allay nervous excitement

Two other cases turned up during my absence, both of which completed their miscarriage, and I cannot help feeling that, if they had been treated with viburnum, the result would have been different One sent for Dr Westby on the third day, the other was treated by another doctor with opium and morphia hypodermically

It does not do to build too much on the result of these few cases, but I have been so constantly foiled in my endeavors heretofore to prevent miscarriage, that I hope to have found in viburnum the sure arrester of uterine action, which we certainly at present do not possess

As recommended by Dr Wilson, I prescribe the solid extract prepared from the liquid extract —*British Medical Journal*, February 27, 1886

THE MANAGEMENT OF PLACENTA PRÆVIA —At the close of an interesting paper on this subject, DR MALCOLM MCLEAN, of New York, offers the following rules in dealing with placenta prævia

First In any case avoid the application of all chemical styptics, which only clog the vagina with inert coagula, and do not prevent hæmorrhage At the very first, the patient should be put in a state of absolute rest—body and mind—and a mild opiate is often desirable at this stage to quiet the irritation

Second Inasmuch as the dangers from *hæmorrhage* are greater than all else to both mother and child, at the earliest moment preparations should be made to *induce* premature labor, and labor being once started, the case should be closely watched to its termination by the accoucheur

Third In primiparæ, the mothers with rigid tissues, the *vagina* should be well distended, by either the colpeurynter or tampon, as an adjuvant to the cervical dilatation

Fourth In the *majority* of cases generally, and in all cases especially where there is reason to believe that rapid delivery may be required, it is more safe to rely upon the *thorough*, *continuous* hydrostatic pressure of a Barnes' dilator than on pressure by the fetal parts

Fifth Where the implantation is only lateral or partial, and where there is no object in hurrying the labor, bipolar version, drawing down a foot, and leaving one thigh to occlude and dilate the os, may be practised according to the method of Braxton Hicks, except in cases where the head presents well at the os, when

Sixth, the membranes should be ruptured, the waters evacuated, and the head encouraged to engage in the cervico vaginal canal

Seventh In the majority of cases, podalic version is to be preferred to application of the forceps within the os

Eighth In some cases, in the absence of sufficient assistance or the necessary instrument, the complete vaginal tampon, in part or wholly of cotton, may be applied and left *in situ* until (within a reasonable time) it is dislodged by uterine contractions and the voluntary efforts of the mother In case of favorable presentation—occiput or breech—the tampon will not materially obstruct the descent of the child, and in some cases the tampon, placenta, and child will be expelled rapidly and safely without artificial assistance

Ninth The dangers of septic infection by means of the tampon or India rubber dilators are so slight, if properly used, as not to be considered as seriously impairing their great value

Tenth Whenever it is possible, dilatation and delivery ought to be *deliberately* accomplished, in order to avoid maternal lacerations

Finally As cases of placenta prævia offer special dangers from post-partum hæmorrhages, septicemia, etc , the greatest care must be exercised in every detail of operation and nursing, to avoid conveying septic material to the system of the mother

Absolute cleanliness, rather than chemical substitutes for that virtue, should be our constant companion in the practice of the obstetric art —*American Journal of Obstetrics* March, 1886

---

[1] In repeated large doses it is apt to give rise to headache

SATURDAY, MARCH 20, 1886

THE DEATH OF DR AUSTIN FLINT, SR

Of the many distinguished physicians of America, distinguished both as original thinkers and clinicians, none have risen to a higher place in the esteem and respect of the professional men of their country, and indeed of medical men the world over, than AUSTIN FLINT For years his name has commanded the respect due to high professional attainments wherever medicine is known as a science The esteem in which he was held abroad may be known by the fact that he was selected to deliver the address in Medicine at the next meeting of the greatest medical association in the world—the British Medical Association, and the estimation placed upon his professional ability at home was shown by his being chosen as the President of the Ninth International Medical Congress, which will meet in the City of Washington in 1887

"Nothing is more estimable," says Voltaire, "than a physician who, having studied nature from his youth, knows the properties of the human body, the diseases which assail it, the remedies which will benefit it, exercises his art with caution, and pays equal attention to the rich and poor" Such a physician and man was Dr Flint a man of great professional learning and attainments, a student of nature, both healthy and diseased, a great thinker and clinician, of a kind and even temper, refined in conversation and manner, great of heart, magnanimous and courtly, not given to criticisms of his professional brethren, not a man who

> "For the poor renown of being smart
> Would leave a sting within a brother's heart"

How aptly may be applied to him the words spoken by him of the lamented Gross his intimate friend "His life, from the beginning to the end of his long professional career, was a life of work —work as a student, a writer, a teacher and a practitioner From first to last he was a diligent student If in his advancing and advanced years he held tenaciously to opinions previously formed, it was not from any lack of knowledge covering recent views, but because they failed to subvert his convictions To hold fast to these after due deliberation was a strong mental characteristic His was not a mind to be carried away by every wind of doctrine He may have been open to the charge of undue tenacity of convictions, but, if so, it was not from a pride of personal opinions, but from a reluctance to relinquish aught that he had been led to believe was true" His life since he began the practice of his profession in Northhampton, Mass, in 1833, was one of continued study of and devotion to medicine, and what he has done to elevate American medicine and medicine as a science is too well known to require repetition here From the very first he made himself known as a practitioner and as a valuable contributor to medical literature His kindness of heart, natural refinement and gentleness enabled him to escape the censure which men so often pay as a tax for being eminent His untiring energy seemed to carry the conviction that "it is better to wear out than to rust out," and his application of his rich experience to present work showed that he was always making his present and all his future the fruit of all his past

Dr Flint's life as an author was singularly successful Few American writers, of any kind, had a style so simple, a diction so faultless And in his success we have a most brilliant example of the truth, which he himself recognized and uttered, that those who aspire to success as authors must begin to write early "How many," said he, "who cherish such an aspiration in the dim future, remain content with present inaction! Continued procrastination is equivalent to indefinite postponement, and the latter to inability Authors in Medicine do not spring like Minerva from the head of Jove" While, in a certain sense, he cannot be called a voluminous writer, his contributions to medical literature were many and very valuable It is probable that no medical man of the century has written so much with so little in it of questionable value As if recognizing that "learning without thought is labor lost, and thought without learning perilous," he combined the two in a manner that is worthy of all imitation All that he wrote was written carefully—as was all that he did—as though there was to be no subsequent retraction and correction of errors made in haste "Reading maketh a full man, conference a ready man, and writing an exact man," and how full was his knowledge, how ready his hand, mind, and pen, and how exact his writings! In the most remote corners of the earth, wherever the science of medicine is known, read or taught, his writings are known, and with them his fame has gone His life is an illustration of the fact that the busiest practitioner may perform great literary labors in conjunction with the other occupations which claim precedence, and are so irregular and time consuming He might have written more, let us be thankful that he wrote so wisely and so well

His success as a practitioner was not less, perhaps, if possible, greater than that as a writer Indeed, it is difficult to say whether he was greater as an author, a teacher or a practitioner, or whether he was more devoted to his profession or his patients In the interests of his patients he abated no energy, nor hesitated to brave any exposure, to make any sacrifice of time and rest, or spend hours in close study and scientific experimentation His manner and language as a teacher were lucid, straightforward and interesting, his voice clear, and he had an earnestness that rarely failed to carry conviction, both to students in the lecture room and his confrères in the medical societies of which he was a member

To the American Medical Association—of which he was the President in 1884, and to which he was ever and at all times most loyal—Dr Flint's death is a severe loss When his State Society formally repudiated the principles of the Association, he promptly severed his connection with the State Society, and was chiefly instrumental in organizing the New York State and County Associations Nevertheless, he was far removed from the medical politician For this his principles were too high, his nature too generous, and his heart,

"Open all day for melting charity,"

too great His long experience with human suffering had caused him to express the wish that he might be spared a long and painful illness when his alloted time should come, and his wish was granted His last work was in the fulfilment of his duty to his pupils—the second duty of every teacher His first—the duty to his patients—he had always performed, as he had that to his professional brethren and his profession His work, which bears the stamp of his individuality, and his character remain imperishable and priceless treasures to Medicine

> "His life was gentle, and the elements
> So mixed in him, that Nature might stand up
> And say to all the world, This is a man!"

THE RESTRICTION OF FLUIDS IN THE TREATMENT OF OBESITY

In our previous issue were set forth Sée's views concerning the inadvisability of limiting the consumption of water by individuals desirous of reducing their superfluous fat As was seen, he is diametrically opposed to German therapeutists As Oertel's methods of diminishing the body fat are attracting universal attention by reason of the striking success that has attended his efforts, we have thought it would be of interest and profit to give a statement of his position with regard to that taken by Sée The eminent French author just named may oppose by theory and practice the views expressed by the Germans at their Congress in Wiesbaden, but he cannot gainsay the brilliant results they have achieved

Oertel insists strongly upon the advisability, nay, necessity, of curtailing the daily consumption of water, but in his published utterances he repeatedly cautions against reducing it below what is required by the system to carry off the products of tissue waste Indeed, Sée appears to us to be fighting imaginary foes if he proceeds on the assumption that the German therapeutists urge their point to the extent of recommending a dry diet A glance at Oertel's and Ebstein's dietaries shows that they allow their patients from 900 to 1,300 c c and 1,750 c c of fluids respectively, that is, 30 to 43 ounces (Oertel), and 60 ounces (Ebstein), daily

Dancel, who tried the effect of a "thirst-cure," proceeded upon the supposition that water aids directly in the digestion of fat and in the production of fat out of the food, since the hydrogen of the water combines with the carbonic acid to create fat Oertel bases his reasons for restricting the consumption of water upon the physiological laws governing the accumulation of adipose tissue, as follows Fat is formed along and upon the adventitia of small blood vessels, arterioles, veinules and the capillaries with which these stand in direct connection At points remote from such vessels it never develops Fat does not exist in the blood primarily as such, but as a lipogenic material This, escaping through the vascular walls, collects upon their exterior in the form of minute flakes or globules, and these later on make up the adipose tissue If, as may occur, the lipogenic material forms oil-drops within the interior of the vessels, along their inner surface, these then pass through the vascular coats and are absorbed by the connective tissue corpuscles of the vessels, whose outer coat then appears puffy and infiltrated

There is good ground for the belief that the permeability of vascular walls is enhanced by sluggishness of their contents or stasis of the circulation, and by their distension Hence, the withdrawal of the fluids of the system will, by overcoming vascular distension and stasis, lessen the escape of fat-forming material from the capillaries Furthermore, the reduction of the bodily fluids produces localized anæmia within areas of adipose tissue and the consequent drying up of the vessels supplying these areas with nutrition So soon, therefore, as the adipose tissue is deprived of its nourishment, it undergoes destructive metamorphosis and disappears by absorption The reduction of fat in this way becomes not strictly a physiological, but rather a "physiologico-pathological" one Such, then, are the considerations which induce Oertel to make a diminution of the bodily fluids a part of his anti fat treatment When necessary to reduce the bulk of liquid in the vessels speedily, *e g*, in cases of circulatory disturbances, he resorts to various methods of sweating the patients These were mentioned in an editorial article in THE JOURNAL of October 24, 1885

In his work Oertel refers to two cases in which obesity was strikingly lessened by diminishing the supply of liquids alone No change was made in the diet, and, as the inclement weather of the winter precluded outdoor exercise, the fat was not consumed by oxydization Before the simple restriction of the amount of water consumed was begun, the fat about the mammary regions and over the abdomen was several centimeters in thickness In the course of a few months it had practically disappeared, leaving the integument separated from the underlying structures by only a thin layer of adipose tissue These cases prove the benefit of the withdrawal of water within certain limits in the treatment of obesity Mark! within certain limits, we repeat, that is, sufficient water must still be supplied to further retrograde metamorphosis and elimination of waste products We can but think that Sée mistakes the actual attitude of the Germans on this question in supposing they endorse so great a restriction of fluids as would produce the evil results noted by Jurgensen in his own case Certainly their practice does not differ so widely as his utterances would lead one to suppose

THE SCIENTIFIC ASPECT OF THE AMERICAN MEDICAL ASSOCIATION

In the three preceding numbers of THE JOURNAL we have endeavored to point out the principles on which the National Association was originally founded, the modifications made from time to time as experience demonstrated their necessity, and the marked success achieved in developing a truly National representative organization embracing all ranks, whether specialist or general practitioner, and all interests, social, educational, scientific and practical But there is one aspect in the progress of development that we have not noticed, because its importance demanded a separate and more careful consideration We allude to the establishment of *Sections* in which to prosecute more successfully the scientific work of each annual meeting

During the first decade of the organization of the Association, all the scientific work, such as the reading of reports and papers, with discussions thereon, was done in general sessions of the whole body, numbering from 350 to 1,000 This brief period was amply sufficient to demonstrate that very little progress could be made in that kind of work with such unwieldy audiences during the time allotted to the annual meetings of the Association Measures were therefore early taken to remedy the evil by so amending the constitutional provisions as to restrict the general sessions of each annual meeting to one half of each day, and allow all interested in any particular department of the science or practice of medicine to meet in separate Sections during the other half of each day, and thereby accomplish ten times more work each day than could be accomplished by all meeting in mass The Sections were first organized at the annual meeting of the Association in New Haven, in 1860, so successfully as to give universal satisfaction At that time each Section was permitted to choose its own officers, Chairman and Secretary, at the opening of the first session, and each Section was expected to close its labors with the close of the annual session of the Association each year The increased facilities afforded in the Sections for scientific work caused a rapid increase in the number of papers presented at each meeting, and soon showed two important defects in their practical working It was found that an important part of the time allotted for the first meeting of the Sections each year was occupied in the preliminary work of choosing officers and getting ready to work, and the officers thus chosen and hastily inducted into office were often poorly prepared to perform their duties, and as they regarded those duties ended at the close of the annual meeting, there were practically no officers of Sections in the interim to be preparing the work in an orderly manner for the next annual session

These evils were partially remedied after a few years by adopting a by-law requiring the General Committee on Nominations to nominate and the

Association to elect the Chairman and Secretary of each Section for the ensuing year, and to require the Chairman of each Section to prepare for the general sessions a brief address on the advancements made in the branches included in his Section during the preceding year This change contributed much to give dignity and importance to the officers of the Sections, and increased their efficiency in promoting the amount of practical work done But the Nominating Committee, being composed of one from each State represented in the annual meeting, had but little knowledge concerning the individuals who were most efficient and faithful in the work of the several Sections, and sometimes elected for officers men who had never attended the Sections to which they were assigned more than two or three times, to the neglect of others who had worked faithfully and efficiently in the same Sections for years This led to the conviction that the members of each Section should have the privilege of nominating their own officers, and an amendment to the by laws for this purpose was proposed and is to be acted upon at the coming meeting in St Louis

If the amendment be so drawn as to require each Section to nominate its officers for the ensuing year on the second day of each annual meeting, when the Section is generally the most full and the most favorable time is afforded for making good selections, it will undoubtedly be a decidedly practical improvement It would at once impel those who might be ambitious for official distinction in the Sections to earn it by faithful attendance and good work in the Section itself, instead of giving their attention to the members of the general Nominating Committee Another amendment of the by laws relating to the Sections is worthy of careful consideration The institution of Sections in connection with the Association in 1860 for the better advancement of the scientific interests of the profession, without impairing to any degree the social and educational, was followed by so rapid a development and multiplication of specialties in our country as well as elsewhere, that the time allotted to the Sections each year did not prove adequate for the proper reading and discussion of the many contributions that were offered Nor were the official positions numerous enough to accommodate those more ambitious for advancement And as there has always been a class in the profession, more numerous, perhaps, in the chief cities in the Eastern or older States than elsewhere, who did not like the full representative organization adopted, but advocated a more self electing and narrower governing council, they readily joined with those who did not find adequate room and time for them in the respective Sections, and commenced the organization of National associations of exclusive specialists, incorporating their favorite idea of either a limited membership or more limited governing council, and the whole membership elective only by the society or its council These associations of specialists have continued to increase until, with the National Association of Internal Medicine and Pathology, the organization of which has just been announced, they embrace the entire circle of known specialties Of course the special organizations divert from the Sections of the Association many valuable workers, who cannot well find time to attend both the same year.

If the present proposition for a better mode of selecting officers for the Sections of the Association should be adopted, and another simply allowing each Section to extend the time of its annual session beyond that of the general body whenever work of interest and importance required it, or to hold a second meeting separately at another part of the year if necessary, always reporting the results of their work to the Permanent Secretary of the Association, these Sections would afford every possible facility for the cultivation of any special department of the whole field of medicine that can be afforded by any of the independent special organizations In addition, they would give to the specialists themselves the very great advantage of having all their important papers and discussions early placed before a very large proportion of all classes of the profession through THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, instead of being limited, as now in their Transactions, almost exclusively to the narrow circle of their own members If it be said that THE JOURNAL would not be adequate to the publication of so large an amount of material, the obvious reply is that the capacity of THE JOURNAL admits of any degree of increase that the increased patronage may demand. Further, it is a mutual advantage both to the specialist and non-specialist that they be frequently brought into social contact, and the former be permitted to present his papers before audiences made up in part of the latter, for it is from them that he must derive much of his patronage

Hence, to improve the organization of the Sections and extend the time allowed for their work, as we have indicated, would afford the highest degree of advantage for cultivating the scientific interests of the profession in every direction, and yet preserve and increase the efficiency of the general representative organization for its valuable re unions, fraternizations, and educational advantages, as well as the ready means it affords for harmonizing and concentrating the general sentiments of the profession in favor of such sanitary and other legislation as is required for the interests of the people In the midst of the controversies in regard to Ethical Codes during the last few years, and still more in the dissatisfaction of a few influential parties concerning the action of the American Medical Association in regard to the preliminary organization of the Ninth International Medical Congress, we have heard in certain quarters the most inconsiderate denunciation of the National Association as having passed the day of its usefulness, and many suggestions have been made for a new organization to rival and finally supersede it altogether The plan for this purpose, however, which has been blindly hinted at in correspondence running through a dozen or fifteen years past, and which is at present rapidly maturing, has been carefully kept from open public discussion The plan is simply to complete the circle of National organizations of specialists in such a manner that their entire management will be centred in a comparatively few individuals, yet careful to include as many prominent or influential parties as is practicable, and when the favorable time arrives the whole are to be united by some plan of confederation to constitute one general head, to take the place of the present National organization

It requires but a moderate degree of investigation to see clearly that the execution of such a plan would entirely fail to develop a general organization that would constitute in any sense a representation of the profession of the United States The whole series of special organizations would embrace an aggregate of not more than 1000, three fourths of whom would be specialists from the larger cities, with the whole mass of 50,000 hard working, intelligent general practitioners entirely out, with no part or voice in the matter To call such an arrangement a National organization of the medical profession of this country, would be a misuse of words It would be simply a confederation of organized specialism on the one hand, and an unorganized general profession on the other, with the self complacency and arrogance of the one constantly deepening the prejudices and intensifying the contempt of the other Yet such is the tendency of the discontented elements now losing no opportunity to disparage the truly representative organization of the whole profession, which has been maturing for forty years under the leadership of the American Medical Association

SOCIETY PROCEEDINGS

SUFFOLK DISTRICT MEDICAL SOCIETY

SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE

ALBERT N BLODGETT, M D, SECRETARY

January 13, 1886 The meeting was called to order at eight o'clock, by DR F I KNIGHT, Chairman

DR E O OTIS read a paper entitled

SOME OBSERVATIONS ON HEALTH RESORTS

(See page 316)

DR BARNES said that he had been much disappointed in the benefit to be derived from a change of climate to some of the most noted of our resorts This was illustrated by the description of a trip made by a patient of Dr Barnes's who was advised to go for the winter to Bermuda for a pulmonary trouble He sailed from New York in a leaky vessel stormy weather prevailed during the entire passage, and the patient was frequently drenched with salt water A few days after arrival the patient was seized with rheumatic fever, and suffered much He returned after an absence of six weeks, much worse than when he went away, and died a few days after arrival at his home

As far as climate is concerned, in a health resort, there is no doubt of the necessity that the air shall be more or less humid We keep our houses much too hot, and the air is far too dry for health or comfort A house heated by steam is not comfortable unless the temperature be kept much higher than is necessary in a house warmed by open fires, and particularly if there be ample provision for moisture in the air of the room The most comfortable room in our modern houses is the kitchen, because there is always a change of air going on from the frequent opening of doors, and the draught of the range The teakettle is always on the range, and furnishes a constant supply of steam, which makes the air moist, as proved by the frost on the windows Plants will grow in the atmosphere of the kitchen, but they languish in those parts of the house which are supplied with steam heat, or with hot air from a furnace In moist air, a temperature of 68° is very comfortable, while in air too dry, it is necessary to keep the temperature as high as 75° or 80° in order to feel comfortable

DR A H NICHOLS stated that a recent hasty visit to the South enabled him to confirm the correctness of the statements contained in Dr Otis's paper It is a strange sensation to go in a few hours from a temperature of zero to that of 75° The defect, however, of most health resorts is that the climate is not equable This is especially true in the South The climate of California is better in this respect than that of Florida, and that of Southern Europe is better than that of California The *ideal* climate is doubtless that of Ovatava, in Teneriffe The coldest weather ever known there compares with our June, while the warmest weather is much like our July with the warmest days left out A very striking feature of the climate there is the fact that the warmest period of the day is not at noon, as we are accustomed to observe in the United States, but at a time before noon. During the middle of the day, a fog bank rolls in from the sea and covers the land like a huge umbrella, thus effectually protecting the inhabitants from the extreme heat which would otherwise occur. One fact in connection with the southern parts of the United States is quite surprising, that is, that in many places where one would expect to find malaria, the disease is unknown. This is true in particular at some points near the sea where the air is humid, and we find most of the conditions usually met with in malarious localities. The nearness of the sea, with the presence of iodine and possibly ozone, seem, however, to be the agents of protection to these localities from the poison of malaria.

DR. J. AYER remarked that although he had but little knowledge of the peculiar recommendations of the various health resorts, yet it is becoming more and more evident that physicians must inform themselves of the advantages of the different parts of our country, so as to be able to give an intelligent opinion and suitable advice to those needing a change of climate for any purpose. There are no doubt many places as yet unknown, which possess great advantages as sanitary abodes, and the physician should inform himself in regard to them, as a part of his professional education. In Europe, the science of sanitation has reached a degree of perfection as yet unapproached in America. Patients from our own country cross the ocean to obtain the benefit of a change of climate, which our land, with its immense area and variety of physical conditions, would surely supply.

DR. VINCENT Y. BOWDITCH spoke of the great harm which frequently results from the careless manner in which patients are sent away from home to languish in uncomfortable and crowded boarding-houses, destitute of all the comforts to which they have been accustomed at home, and dependent upon the caprice and interest of hotel keepers of all kinds for everything pertaining to their welfare. Then, too, one is liable to be misled by the careless statements of those who describe the various places of resort. Thus, each locality is vaunted as possessing the "ideal" climate, and other localities are misrepresented. Aiken has been highly recommended by many persons, to the detriment of similar places elsewhere. It is true that this town possesses the advantages of high altitude and pine forests, and the air is doubtless of exceptional purity, but even these qualities are not adapted to all cases. While speaking of remote health resorts, we should not omit to mention those near at hand and which are easily accessible. Thus, Wellesley Hills and Sharon are of great service to many cases of pulmonary disease. The location is high, the air dry, and many of the requisites of a noted resort are attainable at a slight expense of time, strength and money. Patients in both of these places often achieve most gratifying results.
